Abstract

We consider the problem of finding models for logic programs $P$ via fixed points of immediate consequence operators, $T_P$. Certain extensions of syntax invalidate the classical approach, adopted in the case of definite programs, using iterates of $T_P$ and the Knaster-Tarski theorem. We discuss alternatives to the use of this theorem based on elementary notions from topological dynamics. This leads us to consider simple syntactic conditions on $P$, employing level mappings taking values in a countable ordinal $\gamma$, which ensure convergence (to models and fixed points) of the requisite sequences of iterates. We obtain, as a result, a constructive approach to the perfect model semantics of Przymusinski for locally stratified programs, somewhat along the lines of the approach adopted by Apt, Blair and Walker for stratified programs. In particular, when certain inequalities are sharp, we show the existence of unique supported models, which improves Przymusinski’s results for perfect models. This result is obtained by viewing a Scott domain as a generalized ultrametric space, and applying a fixed-point theorem due to Priess-Crampe and Ribenboim. When $\gamma$ happens to be $\omega$, these results extend Fitting’s treatment by metric methods of certain non-stratified programs discussed by Apt and Pedreschi in termination problems.

Subject Classifications: 68Q55, 54H25

Keywords: Logic programming semantics, level mapping, generalized ultrametric space, domain, topological dynamics.

1 Introduction

Computational logic is concerned with the use of logic as a programming language, and broadly consists of the following three components. (1) A syntax, or knowledge representation language, together with a theorem prover or interpreter. In this paradigm, program statements are viewed as axioms, and computation is viewed as deduction from the axioms via the theorem prover. (2) A distinguished minimal model $M$ (a semantics) the purpose of which is to provide any program with its “intended meaning”.

(3) An operator \( T \) with the property that \( M \) is a fixed point of \( T \) (perhaps the least fixed point or a minimal fixed point of \( T \)). Furthermore, one expects (1), (2) and (3) to be connected by a result expressing, on the one hand, completeness and soundness of the theorem prover and, on the other hand, expressing, in terms of \( T \), some form of tractability in relation to the process of determining \( M \).

The classic example of this is provided by definite or positive logic programs. In this case, the syntax is simply the Horn-clause subset of first order predicate logic together with SLD-resolution as the theorem prover. Thus, a definite program \( P \) consists of finitely many clauses of the form \( A \leftarrow A_1, \ldots, A_n \) in which \( A \) and all the \( A_i \) are atoms, and \( n \geq 0 \); the case \( n = 0 \) is an abuse of notation indicating an empty antecedent or body i.e. a unit clause or fact \( A \leftarrow \). Here, \( M \) is the least Herbrand model \( M_P \), \( T \) is the immediate consequence operator \( T_P \), and the requisite connection between the components is established by the following well-known theorem of Apt, Kowalski and van Emden, see [12], in which \( lfp(\lambda P . T_P) \) denotes the least fixed point of \( T_P \).

\textbf{Theorem 1.1} For any definite program \( P \), we have \( M_P = lfp(\lambda P . T_P) = T_P \uparrow \omega(\emptyset) = \{A \in B_P; P \models A\} = \{A \in B_P; P \models A\}. \)

It is worth drawing attention to the fact that the proof of this theorem depends on the lattice-continuity, and hence monotonicity, of \( T_P \) and on an application of the Knaster-Tarski theorem (the fixed-point theorem for complete partial orders).

Despite the rather restricted syntax, it turns out that any partial recursive (computable) function can be computed by some definite program \( P \), so that the class of definite programs is computationally adequate. Nevertheless, there is a lot of current interest in the question of making definite programs more expressive and more flexible for programming purposes, and also in the question of modelling uncertain and non-monotonic reasoning etc. Such questions involve many technicalities, but in essence can be categorized under the following broad headings. (i) The extension of the syntax of definite programs. (ii) The enlargement of the set of truth values one uses to include, say, three, four, many or even infinitely-many truth values. (iii) Changing the underlying logic to permit non-classical logics.

In this paper, the extension of syntax we undertake is to include negated atoms in the bodies of clauses, so that we consider normal logic programs i.e. programs which consist of finitely many clauses of the form \( A \leftarrow A_1, \ldots, A_{k_1}, \neg B_1, \ldots, \neg B_{k_1} \). In such a clause, the symbols \( A \), all the \( A_i \) and all the \( B_j \) are atoms, \( k_1, l_1 \geq 0 \) and the commas stand for conjunction i.e. \( A_1, \ldots, A_{k_1}, \neg B_1, \ldots, \neg B_{k_1} \) denotes \( A_1 \land \cdots \land A_{k_1} \land \neg B_1 \land \cdots \land \neg B_{k_1} \). Moreover, the symbol \( \leftarrow \) denotes the logical connective of material implication. It is worth noting that this change to the syntax does indeed give a considerable gain in expressiveness, and this point is discussed in [1]. As far as issues (ii) and (iii) are concerned, we make no change and therefore we confine ourselves in this paper to just the two truth values \textit{true} and \textit{false}, and deal only with classical first order logic.

Even such a simple change as that we have just made to the syntax leads to the following problem.

\textbf{Problem 1.2} (1) The operator \( T_P \) is no longer monotonic and therefore the Knaster-Tarski theorem is no longer applicable, yet it remains a central problem to find pre-fixed points and fixed points of \( T_P \).

(2) Some form of Theorem 1.1 should still apply in the new context.
One way round the first of these problems is to define powers of the operator \( T_P \) in such a way as to recover monotonicity; this is the way adopted in [1] and it will be further discussed in this paper in §4. An alternative approach is to consider the extent to which the methods of Topology and Analysis can be used as a substitute for the Knaster-Tarski theorem. Indeed, work already undertaken in this direction includes the use of lattice topologies [3, 4]; the use of metrics and the Banach contraction mapping theorem [8], see also [7]; the use of metrics for multi-valued mappings in the case of disjunctive logic programs [11]; the use of the Rutten-Smyth fixed-point theorem for non-expansive operators on quasi-metric spaces [20].

The present paper is concerned with this alternative approach, and our main objective is to explore the use of elementary ideas from topological dynamics within the model theory of logic programs \( P \). Thus, we concentrate on the issue (1) raised in Problem 1.2 and, for reasons which will become clear shortly, do not address (2) at all. In other words, we do not investigate the question of the existence of interpreters and their completeness and soundness in relation to model theory. Indeed, our specific aim is to use ideas connected with convergence of sequences of iterates to find models and supported models \( M \) for \( P \). In fact, the former correspond to pre-fixed points of \( T_P \) (interpretations \( M \) satisfying \( T_P(M) \subseteq M \)), and the latter correspond to fixed points of \( T_P \) (\( M \) is supported if it satisfies \( T_P(M) \supseteq M \), see [1]), and our thinking is based on the following simple observation.

**Observation 1.3** Suppose \( P \) is a normal logic program and \( I \) is an interpretation for \( P \). If the sequence of iterates \((T^n_P(I))_{n \in \mathbb{N}}\) of \( I \) converges in the Cantor topology \( Q \) (see §2) to some \( M \) (it need not so converge), then \( M \) is a model for \( P \) but not necessarily a supported model. If, further, \( T_P \) is continuous in the Cantor topology (it need not be), then \( M \) is a supported model or fixed point of \( T_P \).

**Note 1.4** A similar fact holds for definite logic programs in relation to the Scott topology: Suppose \( P \) is a definite program and \( I \) an interpretation for \( P \). Then the greatest limit \( M \) in the Scott topology of the sequence \((T^n_P(I))_{n \in \mathbb{N}}\) of iterates of \( I \) is a model for \( P \). If, further, the sequence of iterates is monotone increasing (it need not be if \( I \neq \emptyset \)), then \( M \) is a fixed point of \( T_P \). The proof of this follows from [19, Theorem 6] and [20, Lemma 1] and employs the fact that \( T_P \) is always Scott continuous for any definite \( P \). Indeed, taking \( I \) as \( \emptyset \) permits one to recover the classical fixed-point theory for definite programs \( P \), but this will not be discussed further here.

Observation 1.3 will be proved in §2, but for the moment we note that it raises the following question.

**Question 1.5** (1) Can one provide conditions (necessary, sufficient or both necessary and sufficient) for the convergence of sequences \((T^n_P(I))_{n \in \mathbb{N}}\) of iterates in the Cantor topology in terms of the syntax of \( P \)? In particular, can one do this when \( I \) is \( \emptyset \)?

(2) How general is Observation 1.3 as a means of finding pre-fixed points and fixed points of \( T_P \)?

In this paper, we propose to consider this question and to formulate answers to it in terms of level mappings \( l \) and inequalities between the values \( l(A) \) and \( l(A_i), l(B_j) \) in each ground instance \( A \leftarrow A_1, \ldots, A_{k_1}, \overline{A_2}, \ldots, \overline{A_{k_2}}, \overline{B_1}, \ldots, \overline{B_l} \) of every clause in a normal logic program \( P \), where \( l \) takes values in an arbitrary countable ordinal \( \gamma \). Thus, in §2
we establish preliminaries and notation and formulate our main definition. Briefly, $P$ is called (1) \textit{level-decreasing}, respectively, (2) \textit{strictly level-decreasing}, respectively, (3) \textit{semi-strictly level-decreasing} if one has, respectively, the following inequalities holding for all $i, j$: (1) $l(A) \geq l(A_i), l(B_j)$, (2) $l(A) > l(A_i), l(B_j)$, (3) $l(A) \geq l(A_i), l(A) > l(B_j)$.

In fact, see §2 below, the class of programs defined by (3) coincides exactly with the class of locally stratified programs defined by Przymusinski in [16] and in others of his many papers, see in particular [17, 18]. However, the terminology we adopt is more suited to our purposes since we intend to distinguish between the conditions (2) and (3) quite carefully, and the term “locally stratified” does not do this. As a matter of fact, the class of programs defined by Condition (1) is too general and will not be considered here in detail for the same reasons that it is not considered in [16], see §2. Przymusinski [17, 18] has discussed the existence of suitable interpreters for locally stratified programs and related them to model theory. For this reason, as already mentioned, we do not consider procedural semantics at all. Indeed, our results are entirely model-theoretic and may be summarized as follows. In §3 we examine the class defined by Condition (2). It turns out that in this case $TP$ is strictly contracting in the sense of Priess-Crampe and Ribenboim [14, 15] relative to a generalized ultrametric we define in terms of $l$, and which necessitates thinking of a Scott domain as a spherically complete generalized ultrametric space. We show, on using the fixed-point theorem of [14, 15], that in this case $P$ has a unique supported model which coincides with the perfect model of [16]. This improves the results of Przymusinski to the extent that he showed uniqueness only of the perfect models. In particular, if $l$ takes values in $\omega$, then $TP$ is a contraction mapping relative to the ultrametric introduced by Fitting in [8]. We further explore this class in §3, briefly relating it to ideas of current interest in dynamical systems and computing being developed by Edalat in [6] and by us in more detail in [21]. Nevertheless, though of interest, the case $\gamma = \omega$ is too restrictive and it is essential to consider arbitrary countable ordinals $\gamma$ for two reasons. First, doing this allows us to include arbitrary locally stratified programs within our framework. Second, one can show then that the class of strictly level-decreasing programs can compute all partial recursive functions, see [21], which is not the case if one is confined to $\omega$-valued level mappings; some examples of programs which are strictly level-decreasing with respect to level mappings taking values in ordinals greater than $\omega$ are given in Example 3.11. Finally, in §4, we examine semi-strictly level-decreasing programs in depth. In this analysis we recover the perfect model semantics of [16]. However, what is new here is that our approach is very simple and constructive, see Construction 4.4, and our methods are rather different from those employed in [16]. Moreover, we establish recursion equations, see Corollary 4.6, which show very precisely how the iterates involved in the construction evolve. Finally, we note that another simplification obtained by this approach is that we work only with the ordinary iterates of $TP$ rather than with more complicated concepts such as the powers introduced in [1] and defined in §4 for convenience.

It is worth emphasizing the fact that the class of locally stratified programs forms a considerably larger class of programs than the stratified programs, containing, as it does, programs such as the “even numbers” program, see Example 3.12, and others considered by Fitting in [8] which are not stratified. Even the partial answer we give to Question 1.5 in this paper shows, therefore, that the ideas it embodies are a very general means indeed of finding models and supported models for logic programs.

2 Preliminaries and Notation

It will be convenient first to establish some preliminary concepts and definitions which will be used throughout the paper. Our notation is standard and follows [12]. Indeed, all undefined concepts relating to logic programming can be found in [12]. Thus, throughout the paper, \( P \) will denote an arbitrary normal logic program (as defined in the Introduction) whose underlying first order language will be denoted by \( L \). We denote by \( B_P \) the Herbrand base of \( P \) i.e. the set of all ground or variable-free atoms in \( L \). In fact, we shall usually suppose that \( L \) contains at least one function symbol of positive arity, so that \( B_P \) will usually be an infinite set. This assumption is not necessary, but without it topological considerations become rather trivial. Needless to say, all the results we establish apply in full generality whether or not \( L \) contains such a function symbol. Next, we let \( I_P \) denote the set of all Herbrand interpretations for \( P \); as usual each Herbrand interpretation will be identified in a natural way with a subset of \( B_P \), so that \( I_P \) is the power set \( \mathcal{P}(B_P) \) of \( B_P \). We use the notation \( \text{ground}(P) \) to denote the set of all ground instances of clauses in \( P \) i.e. the set of all instances \( A \leftarrow A_1, \ldots, A_{k_i}, \neg B_1, \ldots, \neg B_{l_i} \) of each clause in \( P \) in which \( A, A_i, B_j \) belong to \( B_P \) or, equivalently, contain no variable symbols, see [1]. As already noted, one of the most important concepts in the subject is that of the immediate consequence operator \( T_P : I_P \rightarrow I_P \). This we define next by: \( T_P(I) = \{ A \in B_P; \text{there is a clause } A \leftarrow A_1, \ldots, A_{k_i}, \neg B_1, \ldots, \neg B_{l_i} \in \text{ground}(P) \text{ such that } I \models A_1 \land \cdots \land A_{k_i} \land \neg B_1 \land \cdots \land \neg B_{l_i} \} \). Notice that in classical two-valued logic, the statement \( I \models A_1 \land \cdots \land A_{k_i} \land \neg B_1 \land \cdots \land \neg B_{l_i} \) is equivalent to the statement “\( A_1, \ldots, A_{k_i} \in I \) and \( B_1, \ldots, B_{l_i} \notin I \)”.

Finally, we let \( l \) denote a level mapping so that \( l \) is simply a mapping \( l : B_P \rightarrow \gamma \), where \( \gamma \) denotes an arbitrary countable ordinal. In fact, \( \gamma \) will be regarded as the set of all ordinals \( n \) such that \( n \in \gamma \) i.e. the set of ordinals \( n \) such that \( n < \gamma \). As usual, if \( n = m + 1 \) is the successor of \( m \), then we write \( m = n - 1 \) for the predecessor \( m \) of \( n \). We call \( l \) an \( \omega \)-level mapping in case \( \gamma = \omega \), and also use the notation \( N \) for the set of natural numbers (including zero). We let \( \mathcal{L}_n = \{ A \in B_P; l(A) < n \} \), for \( n \leq \gamma \), and put \( \mathcal{L}_0 = \emptyset \). If \( A \in B_P \) and \( l(A) = n \), we say that the level of \( A \) is \( n \). We call an \( \omega \)-level mapping \( l \) finite if \( \mathcal{L}_n \) is finite for each \( n \in N \). Without loss of generality, we suppose always that the smallest value taken by \( l \) is zero.

Note that \( I_P \) can be naturally identified with \( 2^{B_P} \), where \( 2 \) denotes the set \( \{ 0, 1 \} \). It can, therefore, be endowed with two well-known and important topologies. First, endow \( 2 \) with the Scott topology. Then, as is well-known, the product topology on \( I_P \) coincides with the Scott topology on \( I_P \), viewed as a complete lattice, and it is this fact that underpins the observation made in Note 1.4. Second, endow \( 2 \) with the discrete topology. Then the product topology in this case makes \( I_P \) homeomorphic to the Cantor set. We shall denote this topology on \( I_P \) by \( Q \) and refer to it as the Cantor topology on \( I_P \). Further details of these facts can be found in [19].

There is a simple criterion for convergence of sequences in \( Q \). Again, this can be
Definition 2.1 A sequence \((I_n)\) in \(I_P\) is convergent iff for every \(A \in B_P\) either \(A\) eventually belongs to \(I_n\) or \(A\) eventually does not belong to \(I_n\) (meaning that for all large enough \(n, A \in I_n\) respectively \(A \notin I_n\)). If \((I_n)\) is convergent, then its limit \(I\) is the set \(\{A \in B_P; A\) eventually belongs to \(I_n\}\).

Using this proposition we can prove Observation 1.3.

Proof of Observation 1.3. Let \(I_n\) denote \(T_P^*(I)\) and suppose that \((I_n)\) converges in \(Q\) to \(M\). For the first part, we must show that \(T_P(M) \subseteq M\). Let \(A \in T_P(M)\). Then by definition of \(T_P\), there is a clause \(A \leftarrow A_1, \ldots, A_{k_i}, -B_1, \ldots, -B_{l_i} \in \text{ground}(P)\) such that, for all \(i, j\), we have \(A_i \in M\) and \(B_j \notin M\). Since \((I_n)\) converges to \(M\) in \(Q\), there is, by Proposition 2.1 applied \((k_i + l_i)\)-times, an \(n_0 \in N\) such that, for all \(n \geq n_0\) and for all \(i, j\), we have \(A_i \in I_n\) and \(B_j \notin I_n\). From this and the definition of \(T_P\) it follows that \(A \in I_n\) for all \(n \geq n_0 + 1\) and in turn it now follows from Proposition 2.1 again that \(A \in M\).

Next, if \(T_P\) is continuous in \(Q\), then a simple argument using the uniqueness of limits in \(Q\), which is Hausdorff, shows that \(T_P(M) = M\) as required.

Finally, taking \(P\) to be the following program:

\[
\begin{align*}
r(o) & \leftarrow \\
p(o) & \leftarrow -r(o) \\
p(s(x)) & \leftarrow p(x) \\
q(o) & \leftarrow p(x)
\end{align*}
\]

and taking \(I = \emptyset\) we find that \((I_n)\) converges in \(Q\) to \(M = \{r(o), q(o)\}\), yet \(T_P(M) = \{r(o)\}\) so that \(M\) is not supported.

Of course, in the example just considered, \(T_P\) is not continuous in \(Q\). Indeed, necessary and sufficient syntactic conditions for continuity of \(T_P\) were established in [19]. However, we will not make much use of continuity of \(T_P\) in this work, except in certain of the examples we discuss, and it will be enough to note that a sufficient condition for continuity is for \(P\) to contain no local variables, see [19, Corollary 6] (a variable (symbol) \(y\) is local if it occurs in the body of a clause but not in the head. For example, \(y\) is a local variable in the clause \(p(x) \leftarrow p(y)\)).

Level mappings as defined above have been used in a number of places in the literature on Logic Programming, where they have usually taken values in \(\omega\). For example, they have appeared in the study of termination problems, see [2, 5], in completeness problems, and in [8] to define metrics. We are now in a position to use them to formulate the main definition which we propose to consider in response to Question 1.5, and it will become apparent as we proceed that this paper builds on the work of [1, 8, 16, 17, 18].

Definition 2.2 Let \(P\) be a normal logic program, let \(l : B_P \to \gamma\) be a level mapping and let \(A \leftarrow A_1, \ldots, A_{k_i}, -B_1, \ldots, -B_{l_i} \) denote a typical clause in \(\text{ground}(P)\). We call \(P\):

(1) Level-decreasing (with respect to \(l\)) if the inequalities \(l(A) \geq l(A_i), l(B_j)\) hold for all
and \( j \) in each clause in ground \((P)\).

(2) **Strictly level-decreasing (with respect to \( l \))** if the inequalities \( l(A) > l(A_i) \) hold for all \( i \) and \( j \) in each clause in ground \((P)\).

(3) **Semi-strictly level-decreasing (with respect to \( l \))** if the inequalities \( l(A) \geq l(A_i) \) and \( l(A) > l(B_j) \) hold for all \( i \) and \( j \) in each clause in ground \((P)\).

As noted earlier in the Introduction, semi-strictly level-decreasing programs coincide exactly with the locally stratified programs defined in [16]. Indeed, if \( l : BP \to \gamma \) is a level mapping and we set \( H_n = l^{-1}(n) \) for each ordinal \( n < \gamma \), then in this way we set up a one-to-one correspondence between level mappings \( l \) and local stratifications \( \{H_n; n < \gamma\} \). Of course, Class (2) is a strict subclass and Class (1) a strict superclass of the locally stratified programs. In fact, this latter class of programs, Class (1), can be disposed of immediately as being too general, and it will not be considered further. For example, it contains the program:

\[
p(o) \leftarrow \\
p(s(o)) \leftarrow \\
p(x) \leftarrow \neg p(x)
\]

and in this case \( TP \) has no fixed points at all. Since \( TP \) is continuous here, it follows from Observation 1.3 that the sequence \((TP^n(I))\) can never converge in \( Q \) for any \( I \). It was precisely in order to limit “recursion through negation” that stratified programs were introduced by Apt, Blair and Walker, see [1] and Van Gelder [24], and extended to locally stratified programs by Przymusinski in [16], and why the condition \( l(A) > l(B_j) \) is imposed in (2) and (3) of Definition 2.2.

### 3 Strictly Level-Decreasing Logic Programs

The topology \( Q \) is of course metrizable, and indeed the following ultrametric \( d \) generates \( Q \) whenever we choose a finite level mapping \( l : BP \to \omega \) (see [20]): if \( I_1 = I_2 \), put \( d(I_1, I_2) = 0 \); otherwise, put \( d(I_1, I_2) = 2^{-n} \), where \( I_1 \) and \( I_2 \) differ on some \( A \in BP \) such that \( l(A) = n \), but agree on all atoms of lower level. This metric was introduced by Fitting in [8] where three problematic programs were discussed (the “even numbers” program, a “game” program and also a “transitive closures of graphs” program). In each case, it was shown that \( TP \) is a contraction mapping and hence, by applying the Banach contraction mapping theorem, that each program has a unique supported model. Fitting also discussed a class of programs called “acceptable” by Apt and Pedreschi and encountered in discussions of termination problems in logic programming, see [2, 5]. Indeed, the definition of a strictly level-decreasing program relative to an \( \omega \)-level mapping is implicit in Fitting’s discussion of acceptable programs, although not explicitly given by him in [8]. Notice that the programs just mentioned are not stratified so that the methods of [1] are not applicable to them. It was precisely for this reason that Fitting introduced the metric \( d \) and applied the Banach contraction mapping theorem to discuss their semantics.

It turns out, see Theorem 3.9, that if \( P \) is strictly level-decreasing with respect to an \( \omega \)-level mapping \( l \), then \( TP \) is a contraction mapping relative to the metric \( d \) determined by \( l \), and hence that the Banach contraction mapping theorem may be applied to obtain
is non-empty. In what follows it will simplify matters to denote the ball and for each ordinal terms and notation. For a countable ordinal $\alpha$ and $\beta$, let $\Gamma$ be the set $\{2^{-\alpha}; \alpha < 1\}$ of symbols $2^{-\alpha}$ with ordering $2^{-\alpha} < 2^{-\beta}$ if and only if $\beta < \alpha$.

**Definition 3.3** Let $r : D_C \to \gamma$ be a function, called a rank function, and denote $2^{-\gamma}$ by $0$. Define $d_r : D \times D \to \Gamma_{\gamma+1}$ by

$$d_r(x, y) = \inf \{2^{-\alpha}; c \sqsubseteq x \text{ if and only if } c \sqsubseteq y \text{ for every } c \in D_C \text{ with } r(c) < \alpha\}.$$  

Then $(D, d_r)$ is the generalized ultrametric space induced by $r$.

Notice that the definition just made is closely related to [22, Example 5] which in turn was employed in [20].

It is straightforward to verify that $(D, d_r)$ is indeed a generalized ultrametric space, and we proceed to show next that $(D, d_r)$ is spherically complete. It will be necessary to impose one standing condition on the rank function $r$ namely that, for each $x \in D$ and for each ordinal $\alpha < \gamma$, the set $\{c \in \text{approx}(x); r(c) < \alpha\}$ is directed whenever it is non-empty. In what follows it will simplify matters to denote the ball $B_{2^{-\alpha}}(x)$ by $B_\alpha(x)$. 

Theorem 3.2 Let $(X, d)$ be a spherically complete generalized ultrametric space and let $f : X \to X$ be strictly contracting. Then $f$ has a unique fixed point.
Lemma 3.4 Let \( B_\alpha(x) \subseteq B_\beta(y) \). Then the following statements hold.

1. \( \{ c \in \text{approx}(x) ; r(c) < \beta \} = \{ c \in \text{approx}(y) ; r(c) < \beta \} \).
2. \( B_\alpha = \sup \{ c \in \text{approx}(x) ; r(c) < \alpha \} \) and \( B_\beta = \sup \{ c \in \text{approx}(y) ; r(c) < \beta \} \) both exist.
3. \( B_\beta \subseteq B_\alpha \).

Proof. Since \( x \in B_\alpha(x) \), we have \( x \in B_\beta(y) \) and hence \( d_\alpha(x,y) \leq 2^{-\beta} \). Therefore, the first statement follows immediately from the definition of \( d_\alpha \).

Since the set \( \{ c \in \text{approx}(x) ; r(c) < \beta \} \) is bounded by \( x \), for any \( x \) and \( \beta \), the second statement follows from the consistent completeness of \( D \).

For the third statement, suppose first that \( B_\alpha(x) \subset B_\beta(y) \). Then we immediately have \( \beta < \alpha \) by [14, (1.2)] since \( \Gamma_\alpha \) is totally ordered. Therefore, \( B_\beta = \sup \{ c \in \text{approx}(y) ; r(c) < \beta \} = \sup \{ c \in \text{approx}(x) ; r(c) < \beta \} \sup \{ c \in \text{approx}(x) ; r(c) < \alpha \} = B_\alpha \), and so \( B_\beta \subseteq B_\alpha \) as required. Now suppose that \( B_\alpha(x) = B_\beta(y) = B \), say. If \( \alpha = \beta \), then it is immediate that \( B_\alpha = B_\beta \). So suppose finally that \( \alpha \neq \beta \) and suppose in fact that \( \alpha < \beta \), so that \( B_\alpha \not\subseteq B_\beta \), with a similar argument if it is the case that \( \beta < \alpha \).

We intend to show again that \( B_\alpha = B_\beta \), for which it suffices to obtain \( d_\alpha(B_\alpha, B_\beta) = 0 \). By definition of \( d_\alpha \), \( B_\alpha \) and \( B_\beta \), we see that \( B_\alpha \) and \( B_\beta \) are both elements of the ball \( B \) in question. Suppose that \( d_\alpha(B_\alpha, B_\beta) \neq 0 \). Then there is a compact element \( c_1 \) such that the statement "\( c_1 \subseteq B_\alpha \) iff \( c_1 \subseteq B_\beta \)" is false. Since \( B_\alpha \subseteq B_\beta \), it must be the case that \( c_1 \not\subseteq B_\alpha \) and \( c_1 \subseteq B_\beta \). By [14, (1.1)] any point of a ball is its centre, and so we can take \( y \) to be \( B_\beta \) in the equation established in Part (1). We therefore obtain \( B_\beta = \sup \{ c \in \text{approx}(B_\beta) ; r(c) < \beta \} \). If \( \{ c \in \text{approx}(B_\beta) ; r(c) < \beta \} \) is empty, then \( B_\alpha \) and \( B_\beta \) are both equal to the bottom element of \( D \) and we are done; so suppose \( \{ c \in \text{approx}(B_\beta) ; r(c) < \beta \} \neq \emptyset \). Since \( c_1 \subseteq B_\beta \), there is, by the condition imposed on \( r \), a compact element \( c_2 \) with \( r(c_2) < \beta \) such that \( c_1 \subseteq c_2 \subseteq B_\beta \). But then \( c_2 \not\subseteq B_\alpha \), otherwise we would have \( c_1 \subseteq c_2 \) and \( c_2 \subseteq B_\alpha \), leading to the contradiction \( c_1 \not\subseteq B_\alpha \). But now we have a compact element \( c_2 \) with \( r(c_2) < \beta \) and for which \( c_2 \not\subseteq B_\alpha \) and \( c_2 \subseteq B_\beta \), and this contradicts the fact that \( d_\alpha(B_\alpha, B_\beta) \leq 2^{-\beta} \). Hence, \( B_\alpha = B_\beta \) as required.

Theorem 3.5 Under the standing condition on \( r \), \( (D,d_\alpha) \) is spherically complete.

Proof. By the previous lemma, every chain \( \{ B_\alpha(x) \} \) of balls in \( D \) gives rise to a chain \( \{ B_\alpha \} \) in \( D \) in reverse order. Let \( B = \sup B_\alpha \). Now let \( B_\alpha(x) \) be an arbitrary ball in the chain. It suffices to show that \( B \subseteq B_\alpha(x) \). Since \( B_\alpha \subseteq B_\alpha(x) \), we have \( d_\alpha(B_\alpha, x) \leq 2^{-\alpha} \). But \( d_\alpha \) is a generalized ultrametric and so it suffices to show that \( d_\alpha(B, B_\alpha) \leq 2^{-\alpha} \). For every compact element \( c \subseteq B_\alpha \), we have \( c \subseteq B \) by construction of \( B \). Now let \( c \subseteq B \) with \( c \subseteq D_C \) and \( r(c) < \alpha \). We have to show that \( c \subseteq B_\alpha \). Since \( c \) is compact and \( c \subseteq B \), there exists \( B_\beta \) in the chain with \( c \subseteq B_\beta \). If \( B_\alpha(x) \subseteq B_\beta(x) \), then \( B_\beta \subseteq B_\alpha \) by Lemma 3.4 and therefore \( c \subseteq B_\alpha \). If \( B_\beta(x) \subseteq B_\alpha(x) \), then \( \alpha < \beta \), and since \( c \subseteq B_\beta \), \( c \) is an element of the set \( \{ c \in \text{approx}(x) ; r(c) < \alpha \} = \{ c \in \text{approx}(x) ; r(c) < \alpha \} \). Since \( B_\alpha \) is the supremum of the latter set, we have \( c \subseteq B_\alpha \) as required.

To apply these results to logic programming, we regard \( I_P \) as a domain, under set inclusion, whose set of compact elements is the set \( I_C \) of all finite subsets of \( B_P \), see [20] for related results. We note also that in the special case of the domain \( I_P \), results similar to Theorem 3.5 were obtained in [15].

Definition 3.6 Let \( P \) be a normal logic program and let \( l : B_P \to \gamma \) be a level mapping. We define the rank function \( r_i \) induced by \( l \) by setting \( r_i(I) = \max \{ l(A) ; A \in I \} \) for
the same argument, if for every \( I \in I_P, I = \sup \{ \{ A \}; A \in I \} \).

Our main result in this section is the following theorem.

**Theorem 3.8** Let \( P \) be a normal logic program which is strictly level-decreasing with respect to a level mapping \( l : B_P \to \gamma \). Then \( T_P \) is strictly contracting with respect to the generalized ultrametric \( d_l \) induced by \( l \). Therefore, \( T_P \) has a unique fixed point and hence \( P \) has a unique supported model.

**Proof.** Let \( I_1, I_2 \in I_P \) and suppose that \( d_l(I_1, I_2) = 2^{-\alpha} \).

**Case 1.** \( \alpha = 0 \).

Let \( A \in T_P(I_1) \) with \( l(A) = 0 \). Since \( P \) is strictly level-decreasing, \( A \) must be the head of a unit clause in \( \text{ground}(P) \). From this it follows that \( A \in T_P(I_2) \) also. By the same argument, if \( A \in T_P(I_2) \) with \( l(A) = 0 \), then \( A \in T_P(I_1) \). Therefore, \( T_P(I_1) \cap \mathcal{L}_1 = T_P(I_2) \cap \mathcal{L}_1 \), and hence we have

\[
d_l(T_P(I_1), T_P(I_2)) \leq 2^{-1} < 2^{-0} = d_l(I_1, I_2)
\]

as required.

**Case 2.** \( \alpha > 0 \).

In this case, \( I_1 \) and \( I_2 \) differ on some element of \( B_P \) with level \( \alpha \), but agree on all ground atoms of lower level. Let \( A \in T_P(I_1) \) with \( l(A) \leq \alpha \). Then there is a clause \( A \leftarrow A_1, \ldots, A_k, \neg B_1, \ldots, \neg B_l \) in \( \text{ground}(P) \), where \( k_1, l_1 \geq 0 \), such that for all \( k, j \) we have \( A_k \in I_1 \) and \( B_j \notin I_1 \). Since \( P \) is strictly level-decreasing and \( I_1 \cap \mathcal{L}_\alpha = I_2 \cap \mathcal{L}_\alpha \), it follows that for all \( k, j \) we have \( A_k \in I_2 \) and \( B_j \notin I_2 \). Therefore, \( A \in T_P(I_2) \). By the same argument, if \( A \in T_P(I_2) \) with \( l(A) \leq \alpha \), then \( A \in T_P(I_1) \). Hence we have \( T_P(I_1) \cap \mathcal{L}_{\alpha+1} = T_P(I_2) \cap \mathcal{L}_{\alpha+1} \), and it follows that

\[
d_l(T_P(I_1), T_P(I_2)) \leq 2^{-(\alpha+1)} < 2^{-\alpha} = d_l(I_1, I_2)
\]

as required.

Thus, \( T_P \) is strictly contracting. Therefore, by Theorem 3.2, \( T_P \) has a unique fixed point and therefore \( P \) has a unique supported model as claimed. ■

It is worth noting that the proof of Theorem 3.2, as given in [14, 15], is not constructive and does not provide the means of actually finding the fixed point. By contrast, the results of §4 and of Corollary 4.6, in particular, give constructions for the fixed point obtained by Theorem 3.8.

In the case that \( l \) is an \( \omega \)-level mapping, the argument given in the proof of Theorem 3.8 can be given in exactly the same form with respect to the ultrametric \( d \) introduced by Fitting and defined earlier. In this case, the Banach contraction mapping theorem is sufficient to obtain the fixed point which results, and we have the following theorem.
Theorem 3.9 Suppose $P$ is strictly level-decreasing with respect to an $\omega$-level mapping $l$. Then $T_p$ is a contraction with respect to the ultrametric $d$ with contractivity factor $\leq \frac{1}{2}$. Therefore, $T_p$ has a unique fixed point and hence $P$ has a unique supported model.

Staying with $\omega$-level mappings for a moment, Fitting noted in [8] that when the Banach contraction mapping theorem applies, the fixed point it produces is obtained by considering iterates $T^n_P(I)$ for any $I \in I_P$, and that the sequence of iterates must close off by the first infinite ordinal (so that one does not need to enter the transfinite in this case). In particular, with $I = \emptyset$ we see that $\lim T^n_P(\emptyset)$ is a supported model. Moreover, Fitting noted that all the standard semantics for $P$ (e.g. perfect model, stable model etc.) must coincide when $T_P$ has a unique fixed point. Therefore, we have more generally the following corollary of Theorem 3.8 and Theorem 4.9.

Corollary 3.10 Suppose that $P$ is strictly level-decreasing with respect to an arbitrary level mapping $l : B_P \to \gamma$. Then all semantics for $P$ coincide with the perfect model semantics of [16] which is the unique minimal supported model for $P$.

Example 3.11 (1) Take $P$ to be the following program:

\[
q(o) \leftarrow \neg p(x), \neg p(s(x)) \\
p(o) \leftarrow \\
p(s(x)) \leftarrow \neg p(x)
\]

and define $l : B_P \to \omega + 1$ by $l(p(s^n(o))) = n$ and $l(q(s^n(o))) = \omega$ for all $n \in N$. Then $P$ is strictly level-decreasing and the unique supported model given by Theorem 3.8 is the set $\{p(s^{2n}(o)) ; n \in N\}$.

(2) This time take $P$ to be as follows:

\[
p(o, o) \leftarrow \\
p(s(y), o) \leftarrow \neg p(y, x), \neg p(y, s(x)) \\
p(y, s(x)) \leftarrow \neg p(y, x)
\]

and define $l : B_P \to \omega \omega$ by $l(p(s^k(o), s^j(o))) = \omega k + j$, where $\omega k$ denotes the $k$th limit ordinal. Then $P$ is strictly level-decreasing and its unique supported model is the set $\{p(o, s^{2n}(o)) ; n \in N\} \cup \{p(s^{n+1}(o), s^{2k+1}(o)) ; k, n \in N\}$.

Example 3.12 Take $P$ to be the “even numbers” program:

\[
p(o) \leftarrow \\
p(s(x)) \leftarrow \neg p(x)
\]

with the $\omega$-level mapping $l$ defined by $l(p(s^n(o))) = n$. Then Theorem 3.9 applies to this program (with contractivity factor $\frac{1}{2}$) and produces the set $\{p(o), p(s^2(o)), p(s^4(o)), \ldots\}$ of even numbers as the unique fixed point of $T_P$.

\[\footnote{This terminology is that of M. Barnsley, “Fractals Everywhere”. Academic Press, Inc., San Diego, 1988.}\]
Example 3.13 Consider the following program $P$:

$$p(s(o)) \leftarrow \neg q(o)$$
$$p(x) \leftarrow r(x)$$
$$r(x) \leftarrow p(x)$$
$$q(o) \leftarrow$$

The set $\{q(o), p(s^n(o)), r(s^n(o))\}$ is a fixed point of $T_P$ for every $n$. Therefore, $T_P$ can never satisfy the hypothesis of Theorem 3.8. In fact, this program is semi-strictly level-decreasing, but is never strictly level-decreasing for any level mapping because of the cycle created by the second and third clauses. Such a cycle would be prohibited in a strictly level-decreasing program, and this example shows that a semi-strictly level-decreasing program need not have a contractive immediate consequence operator.

Question 3.14 To what extent is the converse of Theorem 3.8 true? An answer to this question would set limits to the applicability of generalized ultrametrics determined by level mappings.

In fact, the strict converse of Theorem 3.8 is false, as shown by the following example.

Example 3.15 Take $P$ as follows:

$$p(x) \leftarrow$$
$$p(x) \leftarrow p(s(x))$$
$$q(o) \leftarrow$$
$$q(s(x)) \leftarrow q(x)$$

In this case, $T_P$ is a contraction with contractivity factor $\frac{1}{2}$ when we take $l$ to be the $\omega$-level mapping: $l(p(s^n(o))) = l(q(s^n(o))) = n$ for all $n \in N$. But because of the second clause, $P$ is never strictly level-decreasing with respect to any level mapping. However, removing the second clause to obtain a program $P'$ changes nothing i.e. $T_P = T_{P'}$, so that $P$ and $P'$ are subsumption equivalent as defined by Michael Maher in [13]. Thus, the previous question is modulo equivalences of this sort.

The results just discussed suggest connections between computational logic and dynamical systems, and we propose to briefly consider three of these next. This material is being included here in §3, but it is not assumed in what follows that $P$ is necessarily strictly level-decreasing with respect to any level mapping.

First, let us fix a listing $B_P = \{A_0, A_1, A_2, \ldots\}$ of $B_P$ and use it to determine the $\omega$-level mapping $l$ for the present; so that $l(A_n) = n$ for all $n$. Setting $2_{A_i} = 2_i = 2 = \{0, 1\}$ for all $i$, allows us to make the further identification of $I_P$ with $\prod_{i=0}^\infty 2_i$ in which $I \in I_P$ corresponds to the sequence $\alpha = (\alpha_0, \alpha_1, \alpha_2, \ldots)$, where $\alpha_i = 1$ if $A_i \in I$ and equals 0 otherwise. Fitting’s metric now coincides with one often used in symbolic dynamics: $d(\alpha, \beta) = 0$ if $\alpha = \beta$; otherwise $d(\alpha, \beta) = 2^{-n}$, where $n \geq 0$ is the smallest integer such that $\alpha_n \neq \beta_n$ and where of course $\alpha = (\alpha_0, \alpha_1, \alpha_2, \ldots)$ and $\beta = (\beta_0, \beta_1, \beta_2, \ldots)$ are elements of $\prod_{i=0}^\infty 2_i$. Furthermore, under this identification, $T_P$ is conjugate to a sort of shift operator $S_P$ on $\prod_{i=0}^\infty 2_i$. 

12
Example 3.16 As an example of the foregoing comments, the program $P_1$:

$$p(x) \leftarrow p(s(x))$$

corresponds to the shift $(a_0, a_1, a_2, \ldots) \mapsto (a_1, a_2, a_3, \ldots)$ and therefore models chaotic behaviour to the same extent that this shift does this (notice that $T_{P_1}$ and equivalently $S_{P_1}$ has periodic points of every period). The program $P_2$:

$$p(s(x)) \leftarrow p(x)$$

corresponds to the shift $(a_0, a_1, a_2, \ldots) \mapsto (0, a_0, a_1, \ldots)$. The program $P_3$:

$$p(o) \leftarrow p(s(x)) \leftarrow p(x)$$

corresponds to the shift $(a_0, a_1, a_2, \ldots) \mapsto (1, a_0, a_1, a_2, \ldots)$. And the program $P_4$ of Example 3.12:

$$p(o) \leftarrow p(s(x)) \leftarrow \neg p(x)$$

corresponds to the mapping $(a_0, a_1, a_2, \ldots) \mapsto (1, 1 - a_0, 1 - a_1, 1 - a_2, \ldots)$.

For our second observation, we impose the mild condition that $P$ contains at least one unit clause. It follows then that $T_P(\emptyset) \neq \emptyset$, and that we can choose the listing mentioned in the previous paragraph to satisfy the additional condition that $A_0 \in T_P(I)$ for every $I \in I_P$. Note that $P$ is otherwise arbitrary and, in particular, we do not impose the condition on $P$ that $T_P$ be continuous in $Q$ for what follows. Embed $B_P$ into the unit interval $[0, 1]$ by defining $i(A_0) = 0$ and $i(A_n) = 2^{-n}$ for $n \geq 1$. Thus, $B_P$ becomes a compact metric space. Let $V_P$ denote the subspace of $I_P$ consisting of all those elements of $I_P$ which contain $A_0$, and endow $V_P$ with the subspace topology of $I_P$. By virtue of Proposition 2.1, $V_P$ is itself closed and hence compact, and moreover each element of $V_P$ is a non-empty closed subset of $B_P$. In fact, the topology of $V_P$ as a subspace of $I_P$ coincides with that induced by the Hausdorff metric determined by the metric on $B_P$, so that $V_P$ is a closed subspace of Vietoris space, see [6]. Finally, because $A_0 \in T_P(I)$ for all $I \in I_P$, we see that $V_P$ is an invariant set under $T_P$. Thus, $T_P : V_P \to V_P$ is an abstract dynamical system, abstract in the sense that $T_P$ need not be (usually is not) induced by a point map on $B_P$. Since $I_1 = T_P(I)$ belongs to $V_P$ for any $I \in I_P$, iterates of $I$ enter and stay within $V_P$. Thus, any model or fixed point which can be found by means of convergent sequences of iterates can be so found within $V_P$.

Example 3.17 The previous discussion raises the question of syntactic conditions under which $T_P$ is a contraction relative to the Hausdorff metric. For example, the “natural numbers” program $P$ as follows:

$$p(o) \leftarrow p(s(x)) \leftarrow p(x)$$

has the property that $T_P$ is such a contraction with the obvious listing of $B_P$. On the other hand, the “even numbers” program of Example 3.12 does not have this property.
For our third and final observation, suppose that $P = P_1 \cup \ldots \cup P_n$ is a partition of $P$ into $n$ sub-programs in which the definition of each predicate symbol is contained in one of the $P_i$ (the definition of a predicate symbol $p$ is the set of all clauses in $P$ in which the predicate symbol $p$ occurs in the head). We can then write $T_P$ as the union $(\bigcup_{i=1}^n T_{P_i})$ in the sense that for all $I \in I_P$ we have $T_P(I) = (\bigcup_{i=1}^n T_{P_i})(I) = \bigcup_{i=1}^n T_{P_i}(I)$.

In this representation, each of the $T_{P_i}$ is to be thought of as a mapping of $I_P$ into itself rather than as a mapping of $I_P$ into itself.

By means of Proposition 2.1 we have the following result.

**Proposition 3.18** Suppose that $P$ is partitioned as above. Then the following two statements hold.

1. $T_P$ is continuous in $Q$ at a point $I \in I_P$ iff each of the $T_{P_i}$ is continuous in $Q$ at $I$.
2. Suppose that each of the $T_{P_i}$ in the representation above is a contraction relative to Fitting’s metric $d$ with contractivity factor $c_i = 2^{-m_i}$, say. Then $T_P$ is a contraction relative to $d$ with contractivity factor $c = \max\{c_i; i = 1, \ldots, n\}$. Conversely, if $T_P$ is a contraction with factor of contractivity $c$ relative to $d$, then each of the $T_{P_i}$ is a contraction relative to $d$ with contractivity factor $\leq c$. ■

Thus, whenever $T_P$ is continuous in $Q$, $\{I_P; T_{P_1}, \ldots, T_{P_n}\}$ is an iterated function system which is in fact hyperbolic under the conditions of Proposition 3.18(2).

**Example 3.19** The program in Example 3.13 gives rise to an iterated function system which is never hyperbolic for any choice of level mapping $l$. In the program $P$:

\[
q(o) \leftarrow \\
q(s^3(x)) \leftarrow p(x) \\
p(o) \leftarrow \\
p(s^2(x)) \leftarrow \neg p(x)
\]

the definition of $q$ has contractivity factor $\frac{5}{8}$, and the definition of $p$ has contractivity factor $\frac{3}{4}$. Therefore, $P$ determines a hyperbolic iterated function system with contractivity factor $\frac{3}{4}$.

Supposing, finally, that $T_P$ is continuous in $Q$, let $F(I_P)$ denote the set of non-empty compact subsets of $I_P$ endowed with the Hausdorff metric $d_h$ induced by $d$, where $d$ is the metric determined by a finite $\omega$-level mapping $l$. Then, in the standard way, $T_P$ induces a map $F_P : F(I_P) \to F(I_P)$ defined by $F_P(A) = \{T_P(I); I \in A\}$ which is a contraction with contractivity factor $c$ if $T_P$ is such on $I_P$. Thus, $F(I_P)$ is the space of fractals over $I_P$ and $F_P$ is induced from the iterated function system $\{I_P; T_{P_1}, \ldots, T_{P_n}\}$.

These three comments are suggestive of interesting connections between computational logic on the one hand and dynamical systems on the other. In fact, it is ongoing work of the authors to investigate certain notions of dynamical systems, such as attractors, from the point of view of computational logic, and vice-versa. In particular, these ideas are being developed with a view to relating this work to that of Edalat [6] in the context of uncertain (probabilistic) reasoning.
In this section, we take up the study of the class of programs defined by (3) of the Definition 2.2 or, in other words, of the class of locally stratified programs, $P$. This study will be conducted, of course, from our current point of view of attempting to answer Question 1.5, and our main results, as already mentioned in the Introduction, concern a constructive approach to the perfect model semantics of [16].

We begin the details with an example showing that Condition (3) of Definition 2.2 is not, by itself, a necessary one for convergence in $Q$ of sequences of iterates.

Example 4.1 Take the program $P$ as follows:

$$p(x) \leftarrow p(x), \neg p(s(x))$$

$$p(o) \leftarrow$$

It is clear that $P$ is never semi-strictly level-decreasing with respect to any level mapping $l$. However, the sequence of iterates $(T^n_P(\emptyset))$ becomes constant, after the first iterate, with value $\{p(o)\}$. Hence, this sequence trivially converges in $Q$ to the value $\{p(o)\}$, which is a fixed point of $T_P$. Note, in fact, that $T_P$ is continuous in $Q$ in this case.

This example shows that (3), and therefore of course (2), in Definition 2.2 does not provide an entirely general answer to Question 1.5, not even when $T_P$ is continuous in $Q$ and not even for the case $I = \emptyset$. As a matter of fact, Example 3.13 shows that (3) does not provide a sufficient condition either for convergence in $Q$ of sequences of iterates (not even when $P$ is stratified, and Example 3.13 is stratified) since the iterates of $\emptyset$ in this case oscillate between the sets $\{q(o), p(s(o))\}$ and $\{q(o), r(s(o))\}$. Nevertheless, when levels are carefully controlled as in Construction 4.4 below, (3) does provide a sufficient condition for convergence and this fact is used at an important point in the proof of Lemma 4.5 below.

Our approach is closer in spirit to [1] than it is to [16]. In fact, we will make comparisons on several occasions between our results and those of [1]. It therefore will be convenient for the reader if we recall next the notion of stratification as defined in [1] and to record the basic facts and notation used in the construction of the model $M_P$ discussed there.

Let $P$ denote a normal logic program. Then $P$ is said to be stratified if there is a partition $P = P_1 \cup \ldots \cup P_m$ of $P$ such that the following two conditions hold for $i = 1, \ldots, m$:

1. If a predicate symbol occurs positively in a clause in $P_i$, then its definition is contained within $\bigcup_{j \leq i} P_j$.
2. If a predicate symbol occurs negatively in a clause in $P_i$, then its definition is contained within $\bigcup_{j < i} P_j$.

We adopt the convention that the definition of a predicate symbol $p$ occurring in $P$ is contained in $P_1$ whenever its definition is empty. Thus, each predicate symbol occurring in $P$ is defined but it may have empty definition; in particular, $P_1$ itself may be empty.

In order to treat non-monotonic operators, the powers of an operator $T$ mapping a complete lattice into itself were defined as follows:
\[ T \uparrow 0(I) = I \]
\[ T \uparrow (n+1)(I) = T(T \uparrow n(I)) \cup T \uparrow n(I) \]
\[ T \uparrow \omega(I) = \bigcup_{n=0}^{\omega} T \uparrow n(I). \]

Of course, \( T \uparrow n(I) \) is not equal to \( T^n(I) \) unless \( T \) is monotonic. Indeed, the sequence \((T \uparrow n(I))\) is always monotonic increasing. However, this concept can be used to construct a minimal supported model \( M_P \) for any stratified program \( P \) as follows: put \( M_0 = \emptyset, M_1 = T_{P_1} \uparrow \omega(M_0), \ldots, M_m = T_{P_m} \uparrow \omega(M_{m-1}). \) Finally, let \( M_P = M_m. \)

### 4.1 The Case of Arbitrary Level Mappings

We commence with the following simple proposition which in fact is [16, Proposition 5]. However, we include a proof since we need certain details later.

**Proposition 4.2** Every stratified logic program is semi-strictly level-decreasing.

**Proof.** Let \( P = P_1 \cup \ldots \cup P_m \) be a stratification of \( P. \) We define an \( \omega \)-level mapping \( l \) by \( l(A) = i \) if \( A \) is a ground atom whose predicate symbol \( p, \) say, in \( L \) is defined in \( P_{i+1}. \) It is clear that \( P \) is semi-strictly level-decreasing with respect to \( l. \)

Notice that the level mapping defined in the proof just given is not, in general, finite and we will take up this issue later on.

**Definition 4.3** Let \( P \) denote a normal logic program and let \( l : B_P \rightarrow \gamma \) denote a level mapping, where \( \gamma > 1. \) For each \( n \) satisfying \( 0 < n < \gamma, \) let \( P_{[n]} \) denote the set of all clauses in \( \text{ground}(P) \) in which only atoms \( A \) with \( l(A) < n \) occur. We define \( T_{[n]} : \mathcal{P}(\mathcal{L}_n) \rightarrow \mathcal{P}(\mathcal{L}_n) \) by \( T_{[n]}(I) = T_{P_{[n]}}(I). \) The mapping \( T_{[n]} \) is called the immediate consequence operator restricted at level \( n. \)

Thus, the idea formalized by this definition is to “cut-off” at level \( n. \)

**Construction 4.4** Let \( P \) be a semi-strictly level-decreasing normal logic program and let \( l : B_P \rightarrow \gamma \) denote a level mapping, where \( \gamma > 1. \) We construct the transfinite sequence \((I_n)_{n \in \gamma}\) inductively as follows. For each \( m \in N, \) we put \( I_{[1,m]} = T_{[1]}^{\infty}(\emptyset) \) and set \( I_1 = \bigcup_{m=0}^{\infty} I_{[1,m]}. \) If \( n \in \gamma, \) where \( n > 1, \) is a successor ordinal, then for each \( m \in N \) we put \( I_{[n,m]} = T_{[n]}^{\infty}(I_{n-1}) \) and set \( I_n = \bigcup_{m=0}^{\infty} I_{[n,m]}. \) If \( n \in \gamma \) is a limit ordinal, we put \( I_n = \bigcup_{m<n} I_m. \) Finally, we put \( I_{[\gamma]} = \bigcup_{n<\gamma} I_n. \)

The main technical lemma we need is as follows. For its proof, which is by transfinite induction, it will be convenient to put \( I_{[n,m]} = I_n \) for all \( m \in N \) whenever \( n \) is a limit ordinal; thus statement (b) in the lemma makes sense for all ordinals \( n. \)

**Lemma 4.5** Let \( P \) be a normal logic program which is semi-strictly level-decreasing with respect to the level mapping \( l : B_P \rightarrow \gamma, \) where \( \gamma > 1. \) Then the following statements hold.

(a) The sequence \((I_n)_{n \in \gamma}\) is monotonic increasing in \( n. \)
(b) For every \( n \in \gamma, \) where \( n \geq 1, \) the sequence \((I_{[n,m]})\) is monotonic increasing in \( m. \)
(c) For every \( n \in \gamma, \) where \( n \geq 1, \) \( I_n \) is a fixed point of \( T_{[n]}. \)
(d) If \( l(B) < n \) and \( B \not\in I_n, \) where \( B \in B_P, \) then for every \( m \in \gamma \) with \( n < m \) we have \( B \not\in I_m \) and hence \( B \not\in I_{[\gamma]}. \) In particular, if \( l(B) < n \) and \( B \not\in I_{[n+1,m]} \) for some
We establish the recursion equations:

\[ I_{[k+1,0]} = I_k \]
\[ I_{[k+1,m+1]} = I_k \cup T_{P(k)}(I_{[k+1,m]}) \]

and the first is immediate. Putting \( m = 0 \), we have \( I_{[k+1,1]} = T_{[k+1]}(I_k) = T_{[k]}(I_k) \cup T_{P(k)}(I_k) = I_k \cup T_{P(k)}(I_k) = I_k \cup T_{P(k)}(I_{[k+1,0]}) \), using the fact that \( I_k \) is a fixed point of \( T_{[k]} \). Now suppose that the second of these equations holds for some \( m > 0 \). Then \( I_{[k+1,(m+1)+1]} = T_{[k+1]}(I_{[k+1,m+1]}) = T_{[k]}(I_{[k+1,m+1]}) \cup T_{P(k)}(I_{[k+1,m+1]}) = T_{[k]}(I_k \cup T_{P(k)}(I_{[k+1,m+1]})) \), and it suffices to show that \( T_{[k]}(I_k \cup T_{P(k)}(I_{[k+1,m+1]})) = I_k \). So suppose that \( A \in T_{[k]}(I_k \cup T_{P(k)}(I_{[k+1,m+1]})) \). Thus, there is a clause in \( P\) of the form \( A \gets A_1, \ldots, A_{k_i}, \neg B_1, \ldots, \neg B_{l_i} \) where \( A_1, \ldots, A_{k_i} \in I_k \cup T_{P(k)}(I_{[k+1,m+1]}) \) and \( B_1, \ldots, B_{l_i} \notin I_k \cup T_{P(k)}(I_{[k+1,m+1]}) \). But then level considerations and the hypothesis concerning \( P \) imply that \( A_1, \ldots, A_{k_i} \in I_k \) and \( B_1, \ldots, B_{l_i} \notin I_k \). Therefore, \( A \in T_{[k]}(I_k) = I_k \) and we have the inclusion \( T_{[k]}(I_k \cup T_{P(k)}(I_{[k+1,m+1]})) \subseteq I_k \). The reverse inclusion is demonstrated in like fashion, showing that the second of the recursion equations holds with \( m \) replaced by \( m + 1 \) and hence, by induction on \( m \), that it holds for all \( m \).

**Step 2.** We have the inclusions \( T_{P(k)}(I_k) \subseteq T_{P(k)}(I_k \cup T_{P(k)}(I_k)) \subseteq T_{P(k)}(I_k \cup T_{P(k)}(I_k \cup T_{P(k)}(I_k))) \cdots \)

These inclusions are established by methods similar to those we have just employed and we omit the details.

It is now clear from this fact and the recursion equations in Step 1 that \((I_{[k+1,m]}),\) or \((I_{[m,m]}),\) is monotonic increasing in \( m \). Since monotonic increasing sequences converge to their union in \( Q \), see [19, Proposition 9], and \( I_{[k+1,m]} \) is an iterate of \( I_k \), it now follows from Observation 1.3 that \( I_{k+1} \) is a model for \( P_{[k+1]} \).

**Step 3.** If \( B \in B_P \) and \( \ell(B) < k \), then \( B \in I_{k+1} \) iff \( B \in I_k \).

Indeed, if \( B \in I_k \), then it is clear from the recursion equations of Step 1 that \( B \in I_{k+1} \).

On the other hand, if \( B \notin I_k \), then it is equally clear from the recursion equations and level considerations that, for every \( m \in N \), \( B \notin I_{[k+1,m]} \) and hence that \( B \notin I_{k+1} \), as required.
Step 4. $I_{k+1}$ is a supported model for $P_{[k+1]}$.
To see this, suppose that $A \in I_{k+1} = \bigcup_{m=0}^{\infty} I_{[k+1,m]}$. Then there is $m_0 \in N$ such that $A \in I_{[k+1,m_0+1]} = T_{[k+1]}(I_k)$ for all $m \geq m_0$. Thus, $A \in T_{[k+1]}(T_{[k+1]}(I_k)) = T_{[k+1]}(I_{[k+1,m_0]})$. Hence, there is a clause $A \leftarrow A_1, \ldots, A_k, \neg B_1, \ldots, \neg B_i$ in $P_{[k+1]}$ such that each $A_i \in I_{[k+1,m_0]}$ and no $B_j \in I_{[k+1,m_0]}$. But $l(B_j) < k$ for each $j$ since $P$ is semi-strictly level-decreasing. Since $B_j \notin I_{[k+1,m_0]}$, we now see from the recursion equations that $B_j \notin I_k$. From the result in Step 3 we now deduce that, for each $j$, $B_j \notin I_{k+1}$. Since it is obvious that each $A_i$ belongs to $I_{k+1}$, we obtain that $A \in T_{[k+1]}(I_{k+1})$. Thus, $I_{k+1} \subseteq T_{[k+1]}(I_{k+1})$ and therefore $I_{k+1}$ is a supported model for $P_{[k+1]}$, or a fixed point of $T_{[k+1]}$, as required.

Thus, $P(\alpha)$ holds when $\alpha$ is a successor ordinal.

Case 2. $\alpha$ is a limit ordinal.
In this case, it is trivial that $(I_{[\alpha,m]})$ is monotone increasing in $m$. Thus, we have only to show that $I_{\alpha}$ is a fixed point of $T_{[\alpha]}$ i.e. a supported model for $P_{[\alpha]}$, and we show first that $I_{\alpha}$ is a model for $P_{[\alpha]}$. Let $A \in T_{[\alpha]}(I_{\alpha})$. Then there is a clause $A \leftarrow A_1, \ldots, A_k, \neg B_1, \ldots, \neg B_i$ in $P_{[\alpha]}$ such that $A_1, \ldots, A_k \in I_{\alpha}$ and $B_1, \ldots, B_i \notin I_{\alpha}$. Indeed, by the definition of $P_{[\alpha]}$ and the hypothesis concerning $P$, there is $n_0 < \alpha$ such that the clause $A \leftarrow A_1, \ldots, A_k, \neg B_1, \ldots, \neg B_i$ belongs to $P_{[n_0]}$. Since the sequence $(I_{[\alpha,n]})_{n<\gamma}$ is monotone increasing and $I_{\alpha} = \bigcup_{n<\alpha} I_n$, there is $n_1 < \alpha$ such that $A_1, \ldots, A_k \in I_{n_1}$ and $B_1, \ldots, B_i \notin I_{n_1}$. Choosing $n_2 = \max\{n_0, n_1\}$, we have $A \leftarrow A_1, \ldots, A_k, \neg B_1, \ldots, \neg B_i \in P_{[n_2]}$ and also $A_1, \ldots, A_k \in I_{n_2}$ and $B_1, \ldots, B_i \notin I_{n_2}$. Therefore, on using the induction hypothesis we have $A \in T_{[n_2]}(I_{n_2}) = I_{n_2} \subseteq I_{\alpha}$. Hence, $T_{[\alpha]}(I_{\alpha}) \subseteq I_{\alpha}$, as required.

To see that $I_{\alpha}$ is supported, let $A \in I_{\alpha}$. By monotonicity of $(I_{\alpha})_{n<\gamma}$ and the identity $I_{\alpha} = \bigcup_{n<\alpha} I_n$, there is a successor ordinal $n_0 \geq 1$ such that $A \in I_n$ for all $n$ such that $n_0 \leq n < \alpha$. In particular, we have $A \in I_{n_0} = \bigcup_{m=0}^{\infty} I_{[n_0,m]}$. Therefore, there is $m_1 \in N$ such that $A \in I_{[n_0,m_1+1]} = T_{[n_0]}(T_{[n_0]}(I_{n_0-1}))$. Consequently, there is a clause $A \leftarrow A_1, \ldots, A_k, \neg B_1, \ldots, \neg B_i$ in $P_{[n_0]}$ such that $A_1, \ldots, A_k \in T_{[n_0]}(I_{n_0-1}) = I_{[n_0,m_1]} \subseteq I_{n_0} \subseteq I_{\alpha}$ and $B_1, \ldots, B_i \notin I_{[n_0,m_1]}$. But $l(B_j) < n_0 - 1$ for each $j$ and so no $B_j$ belongs to $I_{n_0-1}$ by Step 3 of the previous case. Therefore, by this step, no $B_j$ belongs to $I_{n_0}$ and by iterating this we see that, for every $m \in N$, no $B_j$ belongs to $I_{n_0+m}$. Therefore, no $B_j$ belongs to $I_{\alpha}$. Hence, we have $A \in T_{[n_0]}(I_{\alpha}) \subseteq T_{[\alpha]}(I_{\alpha})$ or in other words that $I_{\alpha} \subseteq T_{[\alpha]}(I_{\alpha})$, as required.

It now follows that $P(n)$ holds for all ordinals $n$, and this completes the proof of (b) and (c). In particular, we see that the recursion equations obtained in Step 1 hold for all ordinals $k$, and we record this fact in the corollary below. Indeed, all that is needed to establish these equations is the fact that each $I_k$ is a fixed point of $T_{[k]}$, and to note that the proof just given shows also that $T_{[\alpha]}$ is a fixed point of $T_{[\alpha]}$. In turn, (d) of the lemma now follows from this observation by iterating Step 3.

The proof of the lemma is therefore complete. ■

It can be seen here, and it will be seen again later, that the importance of (d) is the control it gives over negation in the manner illustrated in the proof just given that $I_{k+1}$ is a supported model for $P_{[k+1]}$. It is also worth noting that the construction produces a monotone increasing sequence by means of a non-monotonic operator, and that Lemma 4.5 plays a rôle here similar to that played by [1, Lemma 10] in [1].
Corollary 4.6 Suppose the hypotheses of Lemma 4.5 all hold. Then:
(1) For all ordinals \( n \) and all \( m \in N \) we have the recursion equations
\[
I_{[n+1,0]} = I_n
\]
\[
I_{[n+1,m+1]} = I_n \cup T_p(n)(I_{[n+1,m]}).
\]
(2) If \( P \) is in fact strictly level-decreasing, then for every ordinal \( n \geq 1 \) we have
\[
I_{[n+1,m]} = I_n \cup T_p(n)(I_n)
\]
for all \( m \in N \), and therefore the iterates stabilize after one step.

Proof. That (1) holds has already been noted in the proof of Lemma 4.5. For (2), it suffices to prove that \( T_p(n)(I_n) = T_p(n)(I_n \cup T_p(n)(I_n)) \). So suppose therefore that \( A \in T_p(n)(I_n \cup T_p(n)(I_n)) \). Then there is a clause \( A \leftarrow A_1, \ldots, A_k, -B_1, \ldots, -B_l \) in \( P(n) \) such that \( A_1, \ldots, A_k \in I_n \cup T_p(n)(I_n) \) and \( B_1, \ldots, B_l \notin I_n \cup T_p(n)(I_n) \). From these statements and by level considerations, we have \( A_1, \ldots, A_k \in I_n \) and \( B_1, \ldots, B_l \notin I_n \). Therefore, \( A \in T_p(n)(I_n) \) so that \( T_p(n)(I_n \cup T_p(n)(I_n)) \subseteq T_p(n)(I_n) \). The reverse inclusion is established similarly to complete the proof.

Statement (2) of this corollary makes the calculation of iterates very easy to perform in the case of strictly level-decreasing programs, and an illustration of this is to be found in Example 4.13.

Theorem 4.7 Suppose that \( P \) is a normal logic program which is semi-strictly level-decreasing with respect to the level mapping \( l : B_P \to \gamma \). Then \( I_{[\gamma]} \) is a minimal supported model for \( P \).

Proof. That \( I_{[\gamma]} \) is a supported model for \( P \) follows from the proof of Lemma 4.5, and so it remains to show that \( I_{[\gamma]} \) is minimal. To do this, we establish by transfinite induction the following proposition: “If \( J \subseteq I_{[\gamma]} \) and \( T_p(J) \subseteq J \), then \( I_n \subseteq J \) for all \( n \in \gamma \), where \( n \geq 1 \), and this clearly suffices. Indeed, \( T_l(I_{[\gamma]}) \subseteq T_p(J) \subseteq J \) and therefore \( J \) is a model for \( I_{[\gamma]} \). But, as already noted in proving Lemma 4.5, \( I_1 \) is the least model for \( P_{[\gamma]} \) by construction, since \( P_{[\gamma]} \) is definite. Therefore, \( I_1 \subseteq J \) and the proposition holds with \( n = 1 \).

Now assume that the proposition holds for all ordinals \( n < \alpha \) for some ordinal \( \alpha \in \gamma \), where \( \alpha > 1 \); we show that it holds with \( n = \alpha \).

Case 1. \( \alpha = k + 1 \) is a successor ordinal, where \( k > 0 \).

We have \( I_k \subseteq J \). We show by induction on \( m \) that \( I_{[k+1,m]} \subseteq J \) for all \( m \). Indeed, with \( m = 0 \) we have \( I_{[k+1,0]} = I_k \subseteq J \). Suppose, therefore, that \( I_{[k+1,m]} \subseteq J \) for some \( m_0 > 0 \). Let \( A \in I_{[k+1,m_0+1]} = T_{[k+1]}(I_{[k+1,m_0]}(I_k)) \). Then there is a clause \( A \leftarrow A_1, \ldots, A_k, -B_1, \ldots, -B_l \) in \( P_{[k+1]} \) such that \( A_1, \ldots, A_k \in T_{[k+1]}(I_k) \) and \( B_1, \ldots, B_l \notin I_{[k+1,m_0]} \). But \( l(B_j) < k \) for each \( j \). Applying Lemma 4.5 (d) we see that no \( B_j \) belongs to \( I_{[\gamma]} \) and consequently no \( B_j \) belongs to \( J \) because \( J \subseteq I_{[\gamma]} \). Since \( I_{[k+1,m_0]} \subseteq J \) by assumption, we have \( A_1, \ldots, A_k \in J \). Therefore, \( A \in T_{[k+1]}(J) \subseteq T_p(J) \subseteq J \), and from this we obtain that \( I_{[k+1,m_0+1]} \subseteq J \) as required to complete the proof in this case.

Case 2. \( \alpha \) is a limit ordinal.

In this case, \( I_\alpha = \bigcup_{n < \alpha} I_n \) and \( I_n \subseteq J \) for all \( n < \alpha \) by hypothesis. Therefore, \( I_\alpha \subseteq J \) as required.

Thus, the result follows by transfinite induction.
**Definition 4.8** Suppose that $P$ is a locally stratified normal logic program, and let $l$ denote the associated level mapping. Given two distinct models $M$ and $N$ for $P$, we say that $N$ is preferable to $M$ if, for every ground atom $A$ in $N \setminus M$, there is a ground atom $B$ in $M \setminus N$ such that $l(A) > l(B)$. Finally, we say that a model $M$ for $P$ is perfect if there are no models for $P$ preferable to $M$.

Notice that the requirement $l(A) > l(B)$ is dual to the requirement $A < B$ relative to the priority relation $<$ defined in [16].

**Theorem 4.9** Suppose that $P$ is a normal logic program which is semi-strictly level-decreasing with respect to a level mapping $l : B_P \rightarrow \gamma$, where $\gamma$ is a countable ordinal. Then $I[P]$ is a perfect model for $P$ and indeed is the only perfect model for $P$.

**Proof.** Suppose that there is a model $N$ for $P$ which is preferable to $I[P]$ (and therefore distinct from $I[P]$); we will derive a contradiction.

First note that $N \setminus I[P]$ must be non-empty, otherwise we have $N \subseteq I[P]$. But this inclusion forces equality of $N$ and $I[P]$ since $I[P]$ is a minimal model for $P$, and therefore $N$ and $I[P]$ are not distinct. This means that there is a ground atom $A$ in $N \setminus I[P]$, which can be chosen so that $l(A)$ has minimum value; let $B$ be a ground atom in $I[P] \setminus N$ corresponding to $A$ in accordance with the definition above, and which satisfies $l(A) > l(B)$.

Next we note that $T[N] \subseteq T_P(N) \subseteq N$, since $N$ is a model for $P$. Hence, $N$ is a model for $P_{[1]}$, which implies that $I_1 \subseteq N$ since $I_1$ is the least model for the definite program $P_{[1]}$. Therefore, $B$ can be chosen so that $B \in I_{n_0} \setminus N$, with minimal $n_0 > 1$. Now $n_0$ cannot be a limit ordinal, otherwise we would have $I_{n_0} = \bigcup_{m<n_0} I_m$, from which we would conclude that $B \in I_{n_0} \setminus N$ for some $m < n_0$ contrary to the choice of $n_0$. Thus, $n_0$ must be a successor ordinal and, therefore, $B$ can be chosen so that $B \in I_{n_0,m_0} \setminus N$, where $m_0$ is such that $I_{[n_0,m_0]} \setminus N = \emptyset$ whenever $m_1 < m_0$; indeed, since $I_1 \subseteq N$, we must have $n_0 > 1$ and $m_0 \geq 1$ also. Consequently, $B \in T_{[n_0]}(I_{[n_0,m_0-1]}) \setminus N$ showing that there is a clause $B \leftarrow C_1, \ldots, C_k, \neg D_1, \ldots, \neg D_{i_k}$ in $P_{[n_0]}$ with the property that each $C_i \in I_{[n_0,m_0-1]}$ and no $D_j \in I_{[n_0,m_0-1]}$. Since $l(D_j) < n_0 - 1$ for each $j$, we see that none of the $D_j$ belong to $I[P]$ by Lemma 4.5 (d). But all the $C_i$; if there are any, must belong to $N$ by the choice of the numbers $n_0$ and $m_0$. Moreover, there must be at least one $D_j$ and indeed at least one belonging to $N$. For if there were no $D_j$ or if we had each $D_j \notin N$, then we would have $B \in T_{P_{[n_0]}}(N) \subseteq T_P(N) \subseteq N$, using again the fact that $N$ is a model for $P$. But this leads to the conclusion that $B \in N$, which is contrary to $B \in I[P] \setminus N$. Thus, there is a $D = D_j \in N \setminus I[P]$, for some $j$, satisfying $l(D) < l(B) < l(A)$. Since $A$ was chosen in $N \setminus I[P]$ to have smallest level, we have a contradiction.

This contradiction shows that $I[P]$ must be a perfect model for $P$ as required. The last statement in the theorem concerning uniqueness of $I[P]$ now follows from [16, Theorem 4], and therefore the proof is complete. $\blacksquare$

Since it is shown in [16] that perfect models are independent of the local stratification, we also have the following result.
Corollary 4.10 If $P$ is a normal logic program which is semi-strictly level-decreasing with respect to two level mappings $l_1$ and $l_2$, then the corresponding models $I_{[P_1]}$ and $I_{[P_2]}$ are equal.

It also follows from [16, Theorem 4] and Theorem 4.9 above that $I_{[P]}$ coincides with the model $M_P$ of [1] when $P$ is stratified. However, for the sake of completeness we next present a proof of this fact using the methods established thus far. To do this, it will be convenient to introduce the concept $T \uparrow n(I)$ for a mapping $T : I_P \rightarrow I_P$ and $I \in I_P$. In fact, $T \uparrow n(I)$ is defined inductively as follows:

$$T \uparrow (n + 1)(I) = T(T \uparrow n(I)) \cup I$$

$$T \uparrow 0(I) = I$$

$$T \uparrow \omega(I) = \bigcup_{n=0}^{\infty} T \uparrow n(I).$$

Theorem 4.11 Let $P$ be a stratified normal logic program with level mapping defined as in the proof of Proposition 4.2. Then $I_{[P]} = M_P$.

Proof. As usual, we take the stratification to be $P = P_1 \cup \ldots \cup P_m$ and we will show by induction that $I_k = M_k$ for $k = 1, \ldots, m$ and that $I_k = M_k$ for $k > m$. From this we clearly have $I_{[P]} = M_m = M_P$ as required.

With the definition of the level mapping we are currently using and with the conventions we have made regarding the stratification, we note first that the equalities $I_{[P]} = \text{ground}(P_1 \cup P_2 \cup \ldots \cup P_k)$ and $P(k-1) = \text{ground}(P_k)$ both hold for $k = 1, \ldots, m$, where $P(k)$ is as defined in the proof of Lemma 4.5.

Now $I_{[P]} = \text{ground}(P_1)$ is definite, even if empty, and so it is immediate that $T_{[P]} \uparrow i(M_0) = T_{[P]} \uparrow i(M_0)$ for all $i$ and that $I_1 = M_1$. So suppose next that $T_{[P_k]} \uparrow i(M_k) = T_{[P_k]} \uparrow i(M_k)$ for all $i$ and that $I_{k+1} = M_{k+1}$ for some $k > 0$. Then $T_{[P_{k+2}]} \uparrow 0(M_{k+1}) = M_{k+1} = T_{[P_{k+2}]} \uparrow 0(M_{k+1})$ and also $I_{[k+2,0]} = I_{k+1} = M_{k+1} = T_{[P_{k+2}]} \uparrow 0(M_{k+1})$. So now suppose that $T_{[P_{k+2}]} \uparrow m(M_{k+1}) = T_{[P_{k+2}]} \uparrow m(M_{k+1})$ and that $I_{[k+2,m]} = T_{[P_{k+2}]} \uparrow m(M_{k+1})$ for some $m > 0$. Then $T_{[P_{k+2}]} \uparrow (m+1)(M_{k+1}) = T_{[P_{k+2}]}(T_{[P_{k+2}]} \uparrow m(M_{k+1})) \cup M_{k+1}$ and $T_{[P_{k+2}]} \uparrow (m+1)(M_{k+1}) = T_{[P_{k+2}]}(T_{[P_{k+2}]} \uparrow m(M_{k+1})) \cup T_{[P_{k+2}]} \uparrow m(M_{k+1})$, and it is clear that $T_{[P_{k+2}]} \uparrow (m+1)(M_{k+1}) \subseteq T_{[P_{k+2}]}(T_{[P_{k+2}]} \uparrow m(M_{k+1}))$. For the reverse inclusion, we note that under our present hypotheses we have $T_{[P_{k+2}]} \uparrow (m+1)(M_{k+1}) = T_{[P_{k+2}]}(T_{[P_{k+2}]} \uparrow m(M_{k+1})) \cup T_{[P_{k+2}]}(T_{[P_{k+2}]} \uparrow m(M_{k+1})) \subseteq T_{[P_{k+2}]}(T_{[P_{k+2}]} \uparrow m(M_{k+1})) \cup M_{k+1}$ or in other words that $I_{[k+2,m+1]} \subseteq T_{[P_{k+1}]}(I_{[k+2,m]}) \cup I_{k+1}$. Since this latter set is equal to $I_{[k+2,m+1]}$ by the recursion equations of Corollary 4.6, the inclusion we want follows from the monotonicity of the sets $I_{[k+2,m]}$ relative to $m$. We conclude, therefore, that $T_{[P_{k+2}]} \uparrow (m+1)(M_{k+1}) = T_{P_{k+2}} \uparrow (m+1)(M_{k+1})$.

Finally, $I_{[k+2,m+1]} = I_{k+1} \cup T_{[P_{k+1}]}(I_{[k+2,m]}) = M_{k+1} \cup T_{[P_{k+1}]}(T_{[P_{k+2}]} \uparrow m(M_{k+1})) = M_{k+1} \cup T_{[P_{k+1}]}(T_{[P_{k+2}]} \uparrow m(M_{k+1})) = T_{[P_{k+2}]} \uparrow (m+1)(M_{k+1}) = T_{[P_{k+2}]} \uparrow (m+1)(M_{k+1})$, by the conclusions of the previous paragraph. Therefore, $I_{[k+2,m+1]} = T_{[P_{k+2}]} \uparrow (m+1)(M_{k+1})$. From this we obtain, by induction, the equality $I_{[k+2,m]} = T_{[P_{k+2}]} \uparrow m(M_{k+1})$ for all $m$ and with it the equality $I_{k+2} = M_{k+2}$ as required.

The details of the induction proof just given also establish the following proposition.

Proposition 4.12 Let $P = P_1 \cup \ldots \cup P_m$ be a stratified normal logic program. Then we have $T_{[P_k]} \uparrow i(M_k) = T_{[P_k]} \uparrow i(M_k)$ for all $i$ and $k = 0, \ldots, m-1$. ■
Example 4.13 (1) Consider again the program in Example 3.13. We have already noted that the sequence of iterates \((T^n_P(\emptyset))\) does not converge in \(Q\) and that this program is stratified (with strata \(P_1 = \{ q(o) \leftarrow \} \) and \(P_2 = \{ p(s(o)) \leftarrow \neg q(o), p(x) \leftarrow r(x), r(x) \leftarrow p(x) \} \). A straightforward computation using the definitions made earlier in connection with stratified programs shows that \(M_1 = T P_1 \uparrow \omega(\emptyset) = \{ q(o) \} \) and that \(M_P = M_2 = T P_2 \uparrow \omega(M_1) = \{ q(o) \} \). On the other hand, the level mapping \(l\) given in the proof of Proposition 4.2 is, in this case, defined by \(l(q(t)) = 0\) and \(l(p(t)) = l(r(t)) = 1\) for all ground terms \(t\). Thus, it turns out that \(I[p] = I_1 = \{ q(o) \} = M_P\) in accordance with Theorem 4.11.

(2) Consider the following program \(P\):

\[
q(o) \leftarrow \\
q(s^2(x)) \leftarrow q(x) \\
p(x) \leftarrow \neg q(x) \\
p(s^2(x)) \leftarrow \neg p(x) \\
p(x) \leftarrow p(x)
\]

This program is not stratified but it is semi-strictly level-decreasing with respect to the level mapping \(l\) in which \(l(q(s^n(o))) = 0\) and \(l(p(s^n(o))) = n + 1\) for all \(n\). In fact, \(I_0\) is the set \(\{ q(s^n(o)); n \in N \} \). Part 2 of Corollary 4.6 applies to the sub-program of \(P\) consisting of the set “definition of \(p\) remove the clause \(p(x) \leftarrow p(x)\)”. This observation simplifies the computation of \(I[p]\) which in fact is the set \(I_0 \cup \{ p(s^n(o)); n \in N, n \text{ not a multiple of } 4 \}\).

Note 4.14 For an arbitrary normal logic program \(P\) (whether stratified or not), let \(M^P\) denote \(T_P \uparrow \omega(\emptyset)\), as defined earlier. By Lemma 4 of [1], \(M^P\) is a model for \(P\). Thus:

(1) Apply this to the “even numbers” program, Example 3.12, which is not stratified. Then \(M^P\) is the set \(B_P\), which is a model for \(P\) but is not a fixed point of \(T_P\). Here of course \(I[p]\) is the set \(\{ p(s^n(o)); n \in N \}\) of even numbers, and clearly \(I[p] \subset M^P\).

(2) For the Example 4.13(2), which again is not stratified, \(M^P\) is the set \(I_0 \cup \{ p(s^n(o)); n \in N \}\). This is a fixed point of \(T_P\), but is not minimal since \(I[p] \subset M^P\). Now partition \(P\) into “strata” \(P = P_1 \cup P_2\), where \(P_1 = \{ q(o) \leftarrow, q(s^2(x)) \leftarrow q(x)\} \) and \(P_2 = \{ p(x) \leftarrow \neg q(x), p(s^2(x)) \leftarrow \neg p(x), p(x) \leftarrow p(x)\} \), and let \(M_2 = T P_2 \uparrow \omega(M_1)\), where \(M_1 = T P_1 \uparrow \omega(\emptyset)\), as defined earlier. Then \(M_2\) is the set \(I_0 \cup \{ p(s^n(o)); n \in N, n \neq 0 \}\) which is another fixed point of \(T_P\), and we have \(I[p] \subset M_2 \subset M^P\).

(3) Taking \(P\) as in Example 4.13(2) but removing the clause \(p(x) \leftarrow p(x)\), we obtain that \(M^P\) is the set \(I_0 \cup \{ p(s^n(o)); n \in N \}\) and that \(M_2\) is the set \(I_0 \cup \{ p(s^n(o)); n \in N, n \neq 0 \}\). Both of these sets are models for \(P\), but neither is a fixed point of \(T_P\) nor a minimal model. Indeed, the only fixed point of \(T_P\) is the set \(I_0 \cup \{ p(s^n(o)); n \in N, n \text{ not a multiple of } 4 \}\). Of course, the uniqueness of the fixed point just noted is a consequence of the fact that \(P\) is in fact strictly level-decreasing with respect to an obvious level mapping.
As can be seen from Example 4.13(2), the sets $I_n$ defined in Construction 4.4 need
not be finite, and this is true whether or not $P$ is stratified. The question therefore
arises as to whether or not it is possible to find a sequence $(J_n)$ of finite sets $J_n$, possibly itera-
tes of some $I$, which converges in $Q$ to $I_P$. In particular, this question
was prompted by the Prolog program written by Hitzler in [9] in order to calculate
iterates and sequences of approximations, and which provided partial motivation for
this study. To finish, we briefly record the facts which show that the answer to these
questions is in the affirmative when $P$ is semi-strictly level-decreasing with respect to
a finite level mapping $l$ and is also stratified by $P = P_1 \cup \ldots \cup P_m$, say. We
make the following construction in which, in order to ease notation, we write $T_i^n$ in place of
$(T_{P_i})_{[n]}$ for all $i$ and $n$.

Construction 4.15 We construct the sequence $(J_n)$ in $I_P$ as follows: (i) $P_1$ is definite
and $L_n$ is finite for every $n$. Hence, for each $n$, the sequence $(T_i^n \uparrow k(\emptyset))_{k \in \mathbb{N}}$
is monotonic increasing with $k$ and is, therefore, eventually constant with value $J_{n,1}$, say. (ii) By
Lemma 10 of [1], we see that for each $n$ the sequence $(T_{i \uparrow}^n \uparrow k(J_{n,i}))_{k \in \mathbb{N}}$
is monotonic increasing with $k$, where $i = 1, \ldots, m - 1$. Hence, it too is eventually constant with
value $J_{n,i+1}$, say, on using the finiteness of the $L_n$ again. Finally, we put $J_n = J_{n,m}$.

The proof of the following theorem may be found in [10].

Theorem 4.16 Let $P$ be a normal logic program which is stratified and is semi-strictly
level-decreasing with respect to a finite level mapping $l$. Then the sequence $(J_n)_{n \in \mathbb{N}}$
as defined in Construction 4.15 converges in $Q$ to $M_P$.

Remark 4.17 We close by comparing the complexities of the different approaches dis-
cussed in the present paper, at least for $\omega$-level mappings.
(i) For strictly level-decreasing programs, it suffices to compute the sequence $(T_P^n(\emptyset))$
to obtain the unique supported model for the program, and therefore only a single limit
is involved.
(ii) Construction 4.15 for programs which are stratified and semi-strictly level-decreasing
with respect to a finite level mapping requires one to compute the single sequence $(J_n)$.
Moreover, each member of this sequence is itself obtained by a finite computation.
Again, therefore, only a single limit is required in this case.
(iii) The approach of Apt, Blair and Walker [1] or the use of Construction 4.4 in the case
of stratified programs requires the computation of the limits of finitely many sequences
$(T_{P_i})(n(M_k))$.
(iv) Using Construction 4.4 for semi-strictly level-decreasing programs involves the com-
putation of the limit of the sequence $(I_n)$, where each $I_n$ is itself obtained by constructing
the sequence $(I_{[n,m]})_m$ and its limit. So, in this case, at most countably many limits
have to be computed. If the program is semi-strictly level-decreasing with respect to
a finite level mapping, the sequence $(I_{[n,m]})_m$ stabilizes after finitely many steps, and
therefore only a single limit needs to be computed.
