

KAON2 Algorithm

Non-tableau reasoning with description logics

C. Braun

Department of Computer Science
University of Dresden

20th January 2006

Outline

- 1 Introduction
 - Motivation
 - A new strategy
- 2 Algorithm
 - Step 1 : Translating $SHIQ(KB)$ into $ALCHIQ^-(KB)$
 - Step 2 : Transformation of $ALCHIQ^-(KB)$ in clausal normal form $\chi(KB)$
 - Step 3 : Saturation of $\chi(KB)$ by Basic Superposition
 - Step 4 : Elimination of function symbols to get $FF(KB)$
 - Step 5 : Final transformation : from $FF(KB)$ to $DD(KB)$
- 3 Conclusion

Semantic Web

Ambition:

Represent **Web metadata** in a **uniformed way**
⇒ Answer **complex queries** much more efficiently

The current situation:

- **RDFS** and **OWL**: Web-ontology languages recently standardized
- Rely on the **DL** formalism:
 - TBox: relations between descriptions
 - ABox: individuals in the knowledge base
- ↗ expressivity ⇒ **tractability** ↘ !

Traditional systems

What about the existing DL reasoners ?

- query answering with **tableau-based algorithms**
- optimizations focused on TBoxes

ABox: tableau-based reasoning perform poorly !

- every element in the ABox is treated individually
⇒ no consideration for sets with **similarities**
- every element in the ABox must be taken into account
⇒ no consideration for **“irrelevant”** ones

Relevant issue: currently, **ABoxes are getting larger...**

Outline

- 1 Introduction
 - Motivation
 - A new strategy
- 2 Algorithm
 - Step 1 : Translating $SHIQ(KB)$ into $ALCHIQ^-(KB)$
 - Step 2 : Transformation of $ALCHIQ^-(KB)$ in clausal normal form $\chi(KB)$
 - Step 3 : Saturation of $\chi(KB)$ by Basic Superposition
 - Step 4 : Elimination of function symbols to get $FF(KB)$
 - Step 5 : Final transformation : from $FF(KB)$ to $DD(KB)$
- 3 Conclusion

Idea : borrow some good recipes...

DL systems can be related to the field of DB management :

- TBox \leftrightarrow **DB Schema**
- ABox \leftrightarrow **DB Instance**

Advantages : sophisticated techniques available

- Join-order optimization : consider sets with **similarities**
- Magic sets transformation : consider only **relevant elements**

Consequence :

Drawbacks of tableau-based algorithms are avoided !

Idea: from DL to DB

Input: A *SHIQ* knowledge base *SHIQ(KB)*

- *SHOIN* corresponds to **OWL-DL**
- *SHIQ* fast as expressive as *SHOIN*
- \Rightarrow Good choice for ontology representation !

Output: A disjunctive datalog program *DD(KB)*

- main language for **logic databases**
 \Rightarrow optimizations available
- if the same ground facts are derived from *SHIQ(KB)* and *DD(KB)*...
... then **query *DD(KB)* instead of *SHIQ(KB)* !**

\Rightarrow Answering query over large ABoxes is much more efficient

Underlying strategy $SHIQ(KB) \rightarrow DD(KB)$

Use only the best side of each...

- 1 First, **TBox and RBox reasoning** only:
Starting with $SHIQ(KB)$, compute all non-ground consequences.
 \Rightarrow Enough for **TBox reasoning tasks** (computing the subsumption hierarchy ...)
- 2 Then, **translation**:
Transform the clauses into a **disjunctive datalog program**.
- 3 Now, **ABox reasoning**:
Use $DD(KB)$ for assertional reasoning.
 \Rightarrow **Query answering** (instance checking ...) is much more efficient !

Why is it (so) complicated ?

Requirement

The decision procedure must be efficiently “simulated” from one formalism to the other:

⇒ Use a resolution decision procedure, but “highly optimized”

⇒ **Basic Superposition**

Some more tasks...

Additional steps to ensure a **correct** and **terminating** transformation.

Overview of the whole algorithm

5 steps

- 1 Translate $SHIQ(KB)$ into $ALCHIQ^-(KB)$
- 2 Transform $ALCHIQ^-(KB)$ in **clausal normal form** $\chi(KB)$
- 3 Saturate $\chi(KB)$ by **Basic Superposition**
- 4 Remove **function symbols** to get $FF(KB)$
- 5 Transform $FF(KB)$ into a **disjunctive datalog** $DD(KB)$

Outline

- 1 Introduction
 - Motivation
 - A new strategy
- 2 Algorithm
 - **Step 1 : Translating $SHIQ(KB)$ into $ALCHIQ^-(KB)$**
 - Step 2 : Transformation of $ALCHIQ^-(KB)$ in clausal normal form $\chi(KB)$
 - Step 3 : Saturation of $\chi(KB)$ by Basic Superposition
 - Step 4 : Elimination of function symbols to get $FF(KB)$
 - Step 5 : Final transformation : from $FF(KB)$ to $DD(KB)$
- 3 Conclusion

Some words about $SHIQ$

The $SHIQ$ knowledge base $SHIQ(KB)$:

$$SHIQ(KB) = KB_R \cup KB_T \cup KB_A$$

- **RBox KB_R :**
 - Transitivity: $Trans(R)$
 - Role inclusions: $R \sqsubseteq S$
- **TBox KB_T :**
 - Concept inclusion: $C \sqsubseteq D$
 - Concept equivalence: $C \equiv D$
- **ABox KB_A :**
 - Membership: $C(a), \neg R(a, b) \dots$
 - (In)equality: $a \approx b, a \not\approx b$

Input: $SHIQ$

A very expressive DL:

Many constructors supported:

- boolean operations : $C \sqcap D, C \sqcup D, \neg C$
- quantifiers : $\exists R.C, \forall R.C$
- number restrictions : $\leq nR.C, \geq nR.C$
- inverse roles : $Inv(R)$

Sometimes a bit too expressive \Rightarrow use fragments:

- $ALCHIQ$: $SHIQ$ without **transitivity axioms** in RBoxes.
- $SHIQ^-$ ($ALCHIQ^-$): $SHIQ$ ($ALCHIQ$) with only **simple roles** (roles without subroles) in number restrictions.

First task: $SHIQ \rightarrow ALCHIQ$

Why is $SHIQ$ too expressive ?

Transitive roles : may threaten the termination of the algorithm
 \Rightarrow use $ALCHIQ$ instead

Remove transitive roles:

- 1 Compute the **concept closure** $clos(KB)$:
~ smallest set of “relevant concepts”
- 2 Adapt the RBox : remove all transitivity axioms $Trans(S)$
- 3 Adapt the TBox : add for the concepts in $clos(KB)$ new **inclusion axioms** encoding transitivity
 \Rightarrow if $S \sqsubseteq R \in KB_R$, then add $\forall R.C \sqsubseteq \forall S.\forall S.C$
- 4 Keep the initial ABox

Output :

An **equisatisfiable** $ALCHIQ$ knowledge base

How hard ?

Polynomial time in the size of $SHIQ(KB)$

Second task: $ALCHIQ \rightarrow ALCHIQ^-$

Why is $ALCHIQ$ still too expressive ?

- **subroles** in number restrictions : may also lead to infinite derivations
- use $ALCHIQ^-$ instead, but that comes only later (Step 3)...

Outline

- 1 Introduction
 - Motivation
 - A new strategy
- 2 **Algorithm**
 - Step 1 : Translating $SHIQ(KB)$ into $ALCHIQ^-(KB)$
 - **Step 2 : Transformation of $ALCHIQ^-(KB)$ in clausal normal form $\chi(KB)$**
 - Step 3 : Saturation of $\chi(KB)$ by Basic Superposition
 - Step 4 : Elimination of function symbols to get $FF(KB)$
 - Step 5 : Final transformation : from $FF(KB)$ to $DD(KB)$
- 3 Conclusion

Classification step (1)

Why do we need FOL clauses in normal form ?

Input required by the **clausal calculus** Basic Superposition
(Step 3)

$\Rightarrow ALCHIQ^-(KB) \rightsquigarrow \chi(KB)$

First idea: direct classification

- 1 directly transform $ALCHIQ^-(KB)$ into a FOL formula $\Pi(KB)$
 $\pi_y(C \sqcup D, X) = \pi_y(C, X) \vee \pi_y(D, X),$
 $\pi(R \sqsubseteq S) = \forall x, y : R(x, y) \rightarrow S(x, y), \dots$
- 2 skolemize $\Pi(KB)$
- 3 use well-known equivalences to put $\Pi(KB)$ in CNF

Clausification step (2)

2 drawbacks :

- exponential blow-up of the size of the KB
- lost of the nice syntactic structure

Second (better) idea: Structural transformation (*renaming*)

- 1 first put the KB in **definitorial normal form**:
 $\exists P.A \sqsubseteq \forall Q.B$: find a simpler expression...
 $\sim \{\exists P.A \sqsubseteq N_1, N_2 \sqsubseteq \forall Q.B, N_1 \sqsubseteq N_2\}$
- 2 apply (extended) direct clausification to this set

A new additional difficulty

Output :

- equisatisfiable set of clauses $\chi(KB)$
- achieved in **polynomial time**
- all clauses classifiable in (only) 8 different **syntactic categories**
⇒ will be useful in Step 3

Side-effect: new function symbols

The **skolemization** may introduce **new function symbols**.
⇒ Query answering may not terminate

Classification step (4)

Example :

$C \sqsubseteq \exists R.C$ translated to the rules:

$\{R(x, f(x)) \leftarrow C(x), C(f(x)) \leftarrow C(x)\}$

If $C(a) \in KB_A$, we derive $\{C(f(a)), C(f(f(a))), \dots\} \rightarrow \infty$

Solution:

Before translating the clauses into $DD(KB)$:

- Render function symbols **redundant** \Rightarrow Step 3
- Remove all function symbols \Rightarrow Step 4

Outline

- 1 Introduction
 - Motivation
 - A new strategy
- 2 Algorithm
 - Step 1 : Translating $SHIQ(KB)$ into $ALCHIQ^-(KB)$
 - Step 2 : Transformation of $ALCHIQ^-(KB)$ in clausal normal form $\chi(KB)$
 - **Step 3 : Saturation of $\chi(KB)$ by Basic Superposition**
 - Step 4 : Elimination of function symbols to get $FF(KB)$
 - Step 5 : Final transformation : from $FF(KB)$ to $DD(KB)$
- 3 Conclusion

Basic Superposition : how did we get there ?

1. Resolution (1965)

Proves theorems in FOL by **refutation** via inference rules
→yes but... search-space may be huge !

2. Ordered Resolution

Reduces the search space for resolution with **ordering constraints**
→yes but... no support for logics with equality !

3. Paramodulation

Adds explicit rules to resolution calculus for **equality reasoning**
→yes but... too many (unnecessary) inferences !

4. Superposition

Refines **ordering restrictions** to deal with equality
→yes but... still not efficient !

5. Basic Superposition

Avoids the need to apply superposition in terms introduced by previous unification steps.
→much better ! and still **sound** and **complete**...

Parameters of BS:

BS needs 2 parameters:

- **ordering** \succ on terms and literals
- **selection function** f

Some room left for a clever choice:

- **ordering:**

$$S = \{C(a), \neg C(x) \vee C(f(x))\}$$

If $\neg C(x) \succ C(f(x))$ we derive $\{C(f(a)), C(f(f(a))), \dots\}$.

\Rightarrow choose $C(f(x)) \succ \neg C(x)$

- **selection function:**

f selects only negative literals.

Helpful to ensure **termination**.

Basic Superposition: 5 inference rules (1)

1. Positive Superposition

$$\frac{(C \vee s \approx t). \rho \quad (D \vee w \approx v). \rho}{(C \vee D \vee w[t]_p \approx v). \theta}$$

where $\sigma = MGU(s\rho, w\rho | \rho)$ and $\theta = \rho\sigma (+ CONSTRAINTS)$

Select some equal terms to be replaced in other terms and remove the corresponding equality axiom after unification.

Example: Positive superposition

$$\frac{(C(x) \vee s \approx t). \{s \mapsto g(x), t \mapsto h(x)\} \quad (C(g(x))) \{x \mapsto f(y)\}}{C(x) \vee [g(x)] \approx [h(x)] \quad C(g([f(y)]))} \equiv \frac{C(x) \vee [g(x)] \approx [h(x)] \quad C(g([f(y)]))}{C(f(y)) \vee C([h(f(y)]))}$$

Basic Superposition: 5 inference rules (2)

2. Negative Superposition

$$\frac{(C \vee s \approx t).\rho \quad (D \vee w \not\approx v).\rho}{(C \vee D \vee w[t]_p \not\approx v).\theta}$$

where $\sigma = MGU(s\rho, w\rho | \rho)$ and $\theta = \rho\sigma (+ CONSTRAINTS)$

Same idea with inequality axioms.

3. Reflexivity resolution

$$\frac{(C \vee s \not\approx t).\rho}{C.\theta}$$

where $\sigma = MGU(s\rho, t\rho)$ and $\theta = \rho\sigma (+ CONSTRAINTS)$

Equality predicates are replaced by their consequences after unification of both equals.

Basic Superposition: 5 inference rules (3)

4. Equality factoring

$$\frac{(C \vee s \approx t \vee s' \approx t').\rho}{C \vee t \not\approx t' \vee s' \approx t').\theta}$$

where $\sigma = MGU(s\rho, s'\rho)$ and $\theta = \rho\sigma$ (+ CONSTRAINTS)

A set of equalities is simplified after the unification of terms involved in different equalities.

Basic Superposition: 5 inference rules (4)

5. Ordered hyperresolution

$$\frac{E_1 \dots E_n \quad N}{(C_1 \vee \dots \vee C_n \vee D). \theta}$$

where: E_i are of the form $(C_i \vee A_i). \rho$, for $1 \leq i \leq n$, N is of the form $(D \vee \neg B_1 \vee \dots \vee \neg B_n). \rho$, σ is the most general substitution such that $A_i \theta = B_i \theta$ for $1 \leq i \leq n$ and $\theta = \rho \sigma$,
 (+ CONSTRAINTS)

An optimized version of classical resolution.

Example: Ordered Hyperresolution

$$\frac{(C(y) \vee \neg R(x, y)). \{ \} \quad (D(x) \vee R(x, f(x))). \{ \}}{(C(y) \vee D(x)). \{ y \mapsto f(x) \}}$$

Outcome of the saturation step (1)

By case-analysis

Recall: the input clauses had a **well-defined syntactic structure**
 \Rightarrow a **case-analysis** reveals all possible forms of an inferred clause C

Conclusion: only 2 possibilities

- C belongs again to a syntactic category
- C is **redundant** (i.e. removable)

Consequence

Termination is guaranteed !

Outcome of the saturation step (2)

How hard ?

Exponential time in the size of the input KB.

Be careful !

Does not work so well with $ALCHIQ$ instead of $ALCHIQ^-$.
⇒ needs an additional transformation, **decomposition**, during Basic Superposition.

Outline

- 1 Introduction
 - Motivation
 - A new strategy
- 2 Algorithm
 - Step 1 : Translating $SHIQ(KB)$ into $ALCHIQ^-(KB)$
 - Step 2 : Transformation of $ALCHIQ^-(KB)$ in clausal normal form $\chi(KB)$
 - Step 3 : Saturation of $\chi(KB)$ by Basic Superposition
 - **Step 4 : Elimination of function symbols to get $FF(KB)$**
 - Step 5 : Final transformation : from $FF(KB)$ to $DD(KB)$
- 3 Conclusion

Recall: function symbols are annoying

Problem

Function symbols in recursive rules **threaten termination** of query answering.

Idea

- $f(a)$ replaced by a_f , $f(x)$ replaced by x_f .
- A new **predicate** S_f is added to encode the relations.

At the same time, **unsafe variables** in a clause get **bound**.

Output

$FF(KB)$ function-free and equisatisfiable with $\chi(KB)$

Outline

- 1 Introduction
 - Motivation
 - A new strategy
- 2 Algorithm
 - Step 1 : Translating $SHIQ(KB)$ into $ALCHIQ^-(KB)$
 - Step 2 : Transformation of $ALCHIQ^-(KB)$ in clausal normal form $\chi(KB)$
 - Step 3 : Saturation of $\chi(KB)$ by Basic Superposition
 - Step 4 : Elimination of function symbols to get $FF(KB)$
 - **Step 5 : Final transformation : from $FF(KB)$ to $DD(KB)$**
- 3 Conclusion

Some words about Disjunctive Datalog Programs

LP language with some particularities:

- FOL signature Σ with equality \approx
- only constants (no function symbol with arity > 0)
- Finite set of rules of the form:

$$A_1 \vee \dots \vee A_n \leftarrow B_1, \dots, B_m$$

with $n, m \geq 0$, A_i and B_j are atoms over Σ .

Prerequisite: safe rules

All variables in the head appear also in the body

\Rightarrow number of constants remain finite

\Rightarrow all models are finite

Straightforward rewriting

Use a well-known logical equivalence :

$$(A \leftarrow B) \equiv (\neg B \vee A)$$

- move the positive literals in the head
- move the negative literals in the body

Is it really a disjunctive datalog program ? \Rightarrow Recall Step 4

- Only constants: Yes, all function symbols removed.
- Safe rules: Yes, unsafe variables bound.

So finally...

Our goal is reached !

Summary

- **A novel algorithm** which reduces a *SHIQ* knowledge base to an equisatisfiable disjunctive datalog program, using Basic Superposition
- **Efficiently implemented** in KAON2, a promising ontology reasoner developed in Karlsruhe
- **Many challenges** remain: support for nominals, non-monotonicity . . .

For Further Information

Boris Motik

Reasoning in Description Logics using Resolution and Deductive Databases.

PhD, 2006.

<http://kaon2.semanticweb.org>

KAON2

Motivation

- New DL reasoner based on this algorithm
- Better performance on large ABoxes than existing systems
- Very promising for further optimizations

Main features

- Java 1.5
- API for ontology manipulation (OWL XML, OWL RDF)
- Storage of ABox assertions in RDBMS
- Support for SPARQL

Architecture

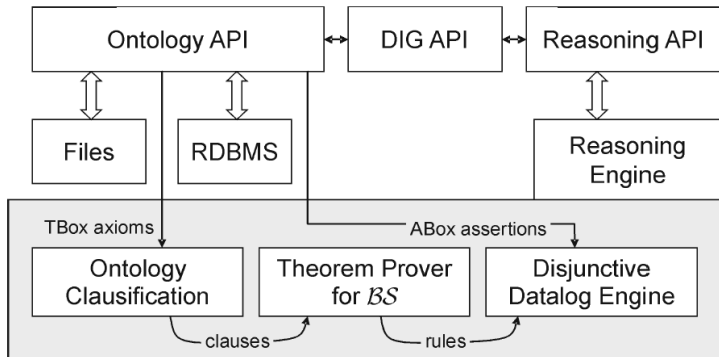

Figure: KAON2 Architecture

Theorem Prover: inference loop

Fairness

Closures split in 2 sets:

- 1 U : unprocessed closures
- 2 W : worked-off closures

\Rightarrow all closures are eventually handled

Initially

W empty, all closures in U .

Theorem Prover: inference loop

Repeat:

- 1 **Non-deterministic choice** of a closure C in U .
- 2 **Redundancy elimination** ($C \rightarrow C'$) 3 possible outcomes:
 - $C' = \{\}$ \Rightarrow *KB unsatisfiable !*
 - C' **redundant** \Rightarrow C' removed
 - Otherwise: go on
- 3 **Backward subsumption**: remove all D in W with $D \sqsubseteq C'$
- 4 **Inferences computation**: saturation \Rightarrow non-tautological conclusions added to U
